Chapter 1

Chapter 1: General introduction

Nicotiana attenuata in its natural environment

Nicotiana attenuata is an annual plant native to the Great Basin desert in the southwestern USA that grows in post-fire environments. *N. attenuata* plants germinate in nitrogen-rich soils after the seeds are exposed to cues contained in wood smoke (Baldwin and Morse, 1994). This synchronized germination behavior creates strong intra-specific competition, and *N. attenuata* plants must allocate their resources to sustain rapid growth and maximize seed set. *N. attenuata* monocultures also experience high herbivore pressure. Presumably in order to maximize the efficiency of their defense while maintaining competitive growth, these plants have developed a complex system of induced responses to defend against or tolerate herbivory (Baldwin, 1998). In its natural habitat, *N. attenuata* is attacked by unpredictable herbivore communities, for example the piercing-sucking herbivores *Tupiocoris notatus* (mirid) and *Empoasca* spp. (leafhopper), the chewing herbivores *Diabrotica undecimpunctata tenella* (spotted cucumber beetle), *Epitrix hirtipennis* and *E. subcrinit* (flea beetles), *Spodoptera exigua* (beet armyworm) and larvae of the specialists *Manduca sexta* (tobacco hornworm) and *M. quinquemaculata* (tomato hornworm). *N. attenuata*'s short generation time (time between seed germination and production of flowers), the complexity of induced defenses, self-compatibility and amenability to transformation by inverted repeated RNA interference and virus induced gene silencing (VIGS) makes it a good model for ecological and molecular studies.

Chapter 1

Plant defense responses

Plants respond to insect attack with a broad array of defenses which are generally divided into indirect and direct defenses. Indirect defenses are plant traits that attract predators and parasitoids of herbivores and thereby reduce the number of feeding herbivores (Kessler and Baldwin, 2002; Arimura et al., 2005). On the other hand, direct defenses comprise all plant traits that affect insect host selection and performance including thorns, trichomes, spines, antinutritive proteins, antidigestive proteins and toxic or deterrent secondary metabolites (Kessler and Baldwin, 2002; Chen, 2008). The term “secondary metabolites” is used to classify metabolites for which no role had yet been found in growth, photosynthesis, reproduction and/or development (Croteau, 2000). Based on their chemical structure and biosynthesis they can be classified into three major groups: 1) terpenes (e.g., mono-, sesqui-, di- and tri-terpenes, saponins), 2) phenolics (e.g., lignins, flavonoids, quinones), and 3) nitrogen-containing compounds (e.g., cyanogenic glycosides, glucosinolates, alkaloids; Croteau, 2000). Some antidigestive proteins interfere with insect digestive enzymes (proteases and amylases) and are thus termed protease and amylase inhibitors (Chen, 2008). In many plant species (e.g., tomato, tobacco, potato, soybean, cowpea) the induction of protease and amylase inhibitors is triggered in response to insect attack. Other antidigestive proteins disrupt the epithelium of the insect digestive tract, including cysteine proteases and lectins (Chen, 2008). Antinutritive proteins like amino acid deaminases and polyphenol oxidases decrease the nutritive value of plant tissues. For example, in tomato, arginase and threonine deaminase deplete the essential amino acids arginine and threonine in the midgut of *M. sexta* larvae and are induced upon *M. sexta* folivory (Chen et al., 2005). Polyphenol oxidases cross-link proteins and oxidize phenolic secondary metabolites to toxic quinones (Kessler and Baldwin, 2002).

Induced versus constitutive defense responses

Some plant defense traits are produced constitutively: for example, in *Arabidopsis thaliana*, glucosinolates are expressed in all tissues and only activated upon herbivory when they are hydrolyzed into toxic isothiocyanates and nitriles (Wittstock and Gershenzon, 2002). On the other hand, a plethora of defenses are synthesized or mobilized, i.e., induced only in response to plant tissue damage. For example, in solanaceous plants (e.g., tomato, tobacco, potato) serine protease inhibitors are induced

Chapter 1

upon herbivory (Lawrence and Koundal, 2002), whereas in maize a cystein protease is induced after lepidopteran attack (Chen, 2008).

Among the best-studied toxic induced defenses is the alkaloid nicotine used by tobacco plants to effectively ward off generalist insects and browsing mammals. Nicotine has been extensively used as an insecticide because it binds to receptors of the excitatory neurotransmitter acetylcholine and is thereby toxic to all heterotrophs with neuromuscular junctions (Baldwin, 2001; Millar and Denholm, 2007). *M. sexta* feeding induces multiple other defenses including protease inhibitors (PIs) and secondary metabolites known as 17-hydroxygeranyl-linalool diterpene glycosides (HGL-DTGs). HGL-DTGs are a diverse group of terpenoid metabolites; and in *N. attenuata* a total of 11 structures were identified which differ from each other in their sugar moieties and the number of malonyl sugar esters (0-2) (Heiling, Schuman et al., 2010). Additionally, two phenylpropanoid-polyamine conjugates (PPCs), caffeoylputrescine (CP) and dicaffeoylspermidine (DCS), are induced upon herbivory and play important roles in *N. attenuata*'s defense response against herbivores (Kaur et al., 2010). When *N. attenuata* plants are engineered to produce reduced amounts of these compounds (HGL-DTGs, nicotine, PPCs and PIs) they become severely compromised in their capacity to survive *M. sexta* attack, and *M. sexta* larvae grow larger (Steppuhn et al., 2004; Zavala et al., 2004; Jassbi et al., 2008; Kaur et al., 2010). Thus these secondary metabolites are required to mount a full defense response against *M. sexta*.

Additionally to its cocktail of direct defenses, *N. attenuata*, like many plants, emits a bouquet of volatile organic compounds (VOCs) upon herbivory (Kessler and Baldwin, 2002). Herbivore-induced VOCs can function as an indirect defense, attracting predators and parasitoids of herbivores to their prey feeding on the attacked plant. Well-described examples are the blend of VOCs release by plants in response to the attack different lepidopteran species including *S. exigua*, *M. sexta* and *Heliothis virescens* among others (Tumlinson and Lait, 2005; Kessler and Baldwin, 2002). Green leaf volatiles (GLVs, C₆-alcohols and -aldehydes) emitted by *N. attenuata* plants in response to *M. sexta* herbivory attract the generalist predator *Geocoris* spp (Allmann and Baldwin, 2010). An additional plant indirect defense is the production of extrafloral nectar rich in carbohydrates and

Chapter 1

proteins. Extrafloral nectar production is induced upon herbivory and it is a nutritious reward for predators of herbivores like wasps, ants and spiders (Heil et al., 2001).

Regulation of defense responses

Plant hormones, or phytohormones, are small signaling molecules with a broad and complex, yet specific action spectrum which often exert their effects at low concentrations. They are known to regulate plant growth, development and responses to biotic and abiotic stress (Davies, 1995; Nemhauser et al., 2006; Bari and Jones, 2009). “Classic” phytohormones with long-known roles in plant development and stress responses are auxins, cytokinins, ethylene (ET), abscisic acid (ABA) and gibberellins (Bari and Jones, 2009); additionally, jasmonates (JAs, derivatives of jasmonic acid [JA]), salicylic acid (SA), and brassinosteroids have been more recently demonstrated as phytohormones (Bari and Jones, 2009). In plant-herbivore interactions, the production of induced defenses is tightly controlled by the fine-tuned orchestration of signal transduction pathways, especially those of JAs, SA and ET. JAs are key players in the orchestration of the plant defense response against herbivores, while the role of ET and SA in herbivore-induced responses is to modulate the JA-dependent defense response via cross-signaling mechanisms (see “Cross-signaling between JAs, SA and ET in plant defense responses”; Reymond and Farmer, 1998; Bari and Jones, 2009).

Oxylipins

Oxylipins are a diverse group of biologically active compounds, including the JAs, derived from the metabolism of polyunsaturated fatty acids (PUFAs; Howe and Schilmiller, 2002). Oxylipin biogenesis in plants is stimulated by diverse stresses including wounding, insect and pathogen attack, and proceeds through distinct enzymatic activities that generate different oxygenated derivatives (Howe and Schilmiller, 2002; Farmer et al., 2003). In one of the first induced chemical reactions, 13-lipoxygenases (13-LOXs) introduce molecular oxygen to the PUFAs linoleic (18:2) and linolenic acid (18:3), converting them to 13-hydroperoxides. In leaves, 13-hydroperoxides serve as substrates for two major biosynthetic pathways induced by wounding and insect herbivory: 1) the

Chapter 1

allene oxide synthase (AOS) pathway and; 2) the hydroperoxide lyase (HPL) pathway, both of which begin in the chloroplast.

The allene oxide synthase (AOS) branch transforms 13-hydroperoxides to 12-oxo-phytodienoic acid (12-OPDA) which in the peroxisome is subjected to 3 rounds of β -oxidation to yield jasmonic acid (JA; Schaller et al., 2004). JA is conjugated to isoleucine (Ile) by JAR enzymes (JAR4 and JAR6 in *N. attenuata*; Staswick and Tiryaki, 2004; Wang et al., 2007) to produce the active signal molecule JA-Ile (Fonseca et al., 2009). JA-Ile binds to the SCF^{coi1} (for Skp1-Cullin-F-box) E3 ubiquitin ligase complex, causing the degradation of JAZ (jasmonate-ZIM domain) repressor proteins and permitting the transcription of jasmonate-elicited genes (Fonseca et al., 2009; Yan et al., 2009). Alternatively, JA may be modified by conjugation to amino acids, sugars or methyl groups; these compounds together with 12-OPDA and JA-Ile are collectively defined as jasmonates (JAs; Schaller et al., 2004). JAs mediate plant defense responses to many herbivores including caterpillars, spider mites, thrips, phloem-feeders, beetles and also to necrotrophic pathogens (Bari and Jones, 2009). In tomato, spider mite and western flower thrip feeding is increased when plants are unable to produce JAs and consequently impair in the accumulation of protease inhibitors (PI; Li et al., 2002). Arabidopsis, the legume *Medicago truncatula* and *N. attenuata* require a functional jasmonate pathway to mount a full defense response against the chewing herbivores *S. littoralis* or *Pieris rapae* and phloem-feeders (Bodenhausen and Reymond, 2007; Gao et al., 2007).

In the hydroperoxide lyase (HPL) branch, HPL cleaves 13-hydroperoxides to generate the green leaf volatiles (GLVs) hexanal and (3Z)-hexenal and (9Z)-traumatol (12-oxo-9Z-dodecenoic acid; Vick and Zimmerman, 1976). GLVs and (9Z)-traumatol may be further modified, isomerized or conjugated (Grechkin, 2002). The role of GLVs as chemical cues during herbivore and pathogen attack has been extensively studied both biochemically and functionally (Croft et al., 1993; Baldwin, 2010). However, less attention has been paid to the metabolism and signaling capacities of the C₁₂ derivatives of the HPL pathway. **In Manuscript III, I contributed to the study of the fluxes and metabolism of C₁₂ derivatives of the HPL pathway in *N. attenuata* plants after wounding and *M. sexta* OS elicitation.**

Chapter 1

Salicylic acid

Salicylic acid (SA) can be synthesized in the chloroplast or in the cytosol from cinnamic acid by two possible pathways (Vlot et al., 2009). In one, a side-chain decarboxylation of cinnamic acid produces benzoic acid, which undergoes a 2-hydroxylation event to yield SA (Lee et al., 1995). Alternatively, cinnamic acid is first 2-hydroxylated to *o*-coumaric acid and then decarboxylated to SA (Lee et al., 1995). Post-synthesis, SA undergoes several modifications such as glycosilation, methylation and amino acid conjugation (Loake and Grant, 2007). SA is involved in responses to biotic and abiotic stresses, as well as growth and developmental processes such as seed germination, photosynthesis, thermogenesis and flowering (Rivas-San Vicente and Plasencia, 2011). SA is also required for establishing systemic acquired resistance (SAR) and thus plays a crucial role in the elicitation of defense responses against biotrophic pathogens such as the production of pathogenesis-related (PR) proteins (Ryals, 1996). For example, in tobacco, infection with the tobacco mosaic virus (TMV) increases SA levels and PR gene expression (Vlot et al., 2009). Similarly, SA levels are highly increased in cucumber after inoculation with tobacco necrosis virus or *Pseudomonas syringae*, and this is followed by SAR development (Vlot et al., 2009).

Ethylene

The biosynthesis of ethylene (ET) occurs in the cytoplasm with the conversion of *S*-adenosyl-methionine (*S*-AdoMet) to ACC (1-aminocyclopropane-1-carboxylic acid) by ACC synthase (ACS, 1-aminocyclopropane-1-carboxylic acid synthase). Finally, ACC is oxidized by ACC oxydase (ACO) to produce ethylene (Wang et al., 2002). ET plays a key role in physiological and developmental processes including seed germination, root, shoot and flower development, fruit ripening, leaf senescence and stress responses (Wang et al., 2002; von Dahl and Baldwin, 2007; Yang et al., 2008). In plant-herbivore interactions, ET is a modulator of the responses triggered by JA (von Dahl and Baldwin, 2007).

Cross-signaling between JAs, SA and ET in plant defense responses.

Although JAs play the prominent role in the induction of defense responses against necrotrophic pathogens and chewing insects in plants, SA and ET can either positively or negatively modulate jasmonate-induced defense responses, and JAs may also positively or

Chapter 1

negatively affect responses moderated by SA and ET (Doherty et al., 1988; Doares et al., 1995; O'Donnell et al., 1996; Reymond and Farmer, 1998; Stotz et al., 2002; Zarate et al., 2007; Diezel et al., 2009; Pieterse et al., 2009). In tomato, it has been shown that the SA produced upon pathogen infection inhibits the accumulation of JA-induced protease inhibitors (PI; Doares et al., 1995). In contrast, ET and JA are required for the wound induction of PI genes in tomato; and this positive regulation of PI genes is suppressed by exogenous application of SA (O'Donnell et al., 1996). In *Nicotiana sylvestris*, the jasmonate- or wound-induced nicotine accumulation is prevented by applying methyl-salicylate (Me-SA) to wounds (Baldwin et al., 1997). A classic example of JAs suppressing SA is the production of the phytotoxin coronatine by *P. syringae* which mimics JA-Ile and suppress SA-dependent plant defense responses, thus allowing bacteria to overcome the plant defense responses. In Arabidopsis, the non-expressor of PR1 (NPR1) is an important regulator of SA-JA cross-talk, though the final defense response depends on ET (Leon-Reyes et al., 2009). Feeding by thrips which do not induce ET requires NPR1 for the SA-mediated suppression of JA responses, whereas *Alternaria brassicicola* (a necrotrophic pathogen) which induces JA and ET bypasses the NPR1 requirement (Leon-Reyes et al., 2009). In *N. attenuata*, NPR1 plays the opposite role by negatively regulating SA production (independently of ET emission), allowing the unfettered elicitation of JA-mediated defenses against herbivores (Rayapuram and Baldwin, 2007). Additionally, in Arabidopsis, the transcription factors WRKY70 and WRKY62 regulate the SA-mediated suppression of JA responses (Li et al., 2004). Moreover, in Arabidopsis, enhanced disease susceptibility 4 (EDS4) functions in SA-dependent defense gene expression after *P. syringae* infection, and *eds4* mutants display enhanced expression of the JA- and ET-dependent defensin gene PDF1.2 (Gupta et al., 2000).

In *N. attenuata* plants the relative production of JAs, SA and ET is herbivore-specific and both plants and insects try to adjust or prevent, respectively, the induction of defense responses. For example, when *N. attenuata* leaves are elicited with OS of the generalist *S. exigua*, it induces the accumulation of SA to levels higher than those induced by OS of the specialist *M. sexta*, whereas *M. sexta* induces the accumulation of higher levels of JA and ET; the lower SA levels in *M. sexta* OS-elicited plants are a consequence of elevated ET levels (Diezel et al., 2009). *N. attenuata* defense responses were attenuated after *S.*

Chapter 1

exigua elicitation when compared to those after *M. sexta* elicitation. Previous studies have shown that after *M. sexta* folivory, *N. attenuata* plants accumulate secondary metabolites such as nicotine, phenolics and PI, the accumulation of which depends on jasmonate production and is modulated by ethylene (von Dahl and Baldwin, 2007). For example, nicotine accumulation is stimulated by JA and repressed by ET (Winz et al., 2001); whereas PI synthesis depends on the synergistic action of JA and ET signaling cascades (von Dahl and Baldwin, 2007).

Plant perception of insect attack

A wide variety of plant species are able to trigger and tailor defense and tolerance responses against lepidopteran larval folivory after perception of elicitors (HAEs: herbivore associated elicitors) present in the oral secretions (OS) of the larvae (Tumlinson and Lait, 2005; Schmelz et al., 2009; Bonaventure et al., 2011). HAEs are diverse in chemical structure and are usually specific to a particular plant-insect association (Bonaventure et al., 2011). HAE perception induces a plant-specific cocktail of direct and indirect defenses (see “Plant defense responses”) as well as tolerance responses (Schwachtje and Baldwin, 2008) against insect feeding. When perceived by the plants, HAEs induce the production of the phytohormones ET and JAs which in turn activate herbivore-specific defense response (Schmelz et al., 2009).

The first HAE identified was the fatty acid-amino acid conjugate (FAC) *N*-(17-hydroxylinolenoyl)-L-Glu or volicitin, isolated from the OS of beet armyworm (*S. exigua*) larvae feeding on *Zea mays* plants (Alborn et al., 1997). Subsequently, many chemically diverse HAEs were identified in the OS of herbivorous species including enzymes, e.g., glucose oxidase (Musser et al., 2002), sulfated α -hydroxy fatty acids termed caeliferins (Alborn et al., 2007), fragments of cell walls (e.g., oligogalacturonides) and peptides released from digested plant proteins (e.g., the proteolytic fragments of chloroplastic ATP synthase γ -subunit, termed inceptins (Schmelz et al., 2006).

FACs belong to a widely distributed family of HAEs present in the OS of a large number of lepidopteran larvae and elicit herbivore-specific responses in several plant

Chapter 1

species including maize (*Zea mays*), soybean (*Glycine max*), eggplant (*Solanum melongena*), black nightshade (*S. nigrum*) and wild tobacco (*N. attenuata*; Alborn et al., 1997; Bonaventure et al., 2011). The main FAC present in *S. exigua* OS is volicitin (*N*-(17-hydroxylinolenoyl)-L-Glu); in *S. litura* OS it is *N*-linolenoyl-L-glutamine rather than volicitin (Yoshinaga et al., 2010). *M. sexta* OS comprises primarily *N*-linolenoyl-L-glutamate (18:3-Glu), *N*-linoleoyl-L-glutamate (18:2-Glu) and *N*-linolenoyl-L-glutamine (18:3-Gln; Halitschke et al., 2001; Diezel et al., 2009).

The role of FACs in caterpillar physiology is not fully understood. In 1974, Collatz and Mommsen found that hydrolysis of the digestive fluids from several insects (crickets, spiders and crayfish) yielded fatty acids and amino acids (Collatz and Mommsen, 1974). Based on this observation they suggested that these compounds could act as emulsifiers of dietary fat. Recently, it has been demonstrated that glutamine-containing FACs are stored forms of glutamine used for the assimilation of nitrogen by the developing lepidopteran larvae (Yoshinaga et al., 2010).

Early signaling events after FAC perception

Since the isolation of volicitin in the OS of *S. exigua* (Alborn et al., 1997) little progress has been made in the identification of the signal transduction mechanisms utilized by plants to respond to HAEs. Two important questions are still unanswered: 1) how are FACs perceived? and 2) what are the molecular mechanisms underlying FAC perception? It has been shown that volicitin induces the depolarization of the plasma membrane of lima bean leaves (Maffei et al., 2004) and that a plasma membrane protein binds to volicitin in *Zea mays* (Truitt et al., 2004).

FACs are major components in the OS of *M. sexta* larvae and are necessary and sufficient to induce most of the defense responses triggered by *M. sexta* larvae feeding on *N. attenuata* plants (Halitschke et al., 2001). One of the earliest known molecular events induced by OS and FACs in *N. attenuata* is the activation of two mitogen-activated protein kinases, SIPK (salicylic acid-induced protein kinase) and WIPK (wound-induced protein kinase; Wu et al., 2007), together with NPR1 (non-expressor of PR1; Kallenbach et al.,

Chapter 1

2010). Transcript levels of SIPK and WIPK are rapidly (within 60 min) and transiently (decline within 120 min) induced after elicitation (Wu et al., 2007). Reduced activity of SIPK and WIPK results in reduced expression of the transcription factors WRKY3 and 6 (Skibbe et al., 2008). To identify novel molecular players of the FAC-/ *M. sexta* OS-induced signal transduction pathway, genome-wide transcriptome studies using “open-architecture” approaches such as differential display PCR (DDRT-PCR) and cDNA- amplified fragment-length polymorphism (cDNA-AFLP) have been performed using *N. attenuata* plants (Hermsmeier et al., 2001; Schittko et al., 2001; Halitschke et al., 2003). Taken together, these studies identified ~ 250 transcripts that were differentially regulated either after 24 h of *M. sexta* larval feeding or after 1 h of multiple sequential events of OS elicitation. Some of the genes identified in these studies have been demonstrated to participate in insect defense mechanisms (Kang et al., 2006; Lou and Baldwin, 2006; Schwachtje et al., 2006). The fast development of high-throughput gene sequencing in combination with new “open-architecture” techniques for quantification of gene expression has opened-up the possibility of performing genome-wide transcriptome studies in organisms from which no massive nucleotide sequence information is yet available as in the case of *Nicotiana attenuata*. Serial analysis of gene expression (SAGE) is a technique that allows absolute quantification of mRNA abundance by quantifying the relative frequencies of individual short (13 nt) transcripts signatures (tags; Velculescu et al., 1995). Further development of the SAGE technique allowed the generation of 26 nt tags (SuperSAGE; Matsumura et al., 2005) which substantially improved the annotation of tags when aligned with sequences in public nucleotide databases (Matsumura et al., 2003). In the SuperSAGE technique the detection of transcripts is proportionally correlated to the scale of DNA sequencing and in combination with next generation sequencing (NGS) allows for the detection and analysis of very low-abundance transcripts (frequently encoding for regulatory components; Matsumura et al., 2005). **In Manuscript I, I identified genes encoding for potential regulatory components of the FAC-mediated responses using the SuperSAGE technique in combination with next generation sequencing (NGS).** In line with the search for novel molecular players, I quantified the early changes (within 30 min) in the transcriptome of *N. attenuata* plants after a single event of 18:3-Glu elicitation. I concentrated on low-abundance transcripts that were rapidly and transiently induced after

Chapter 1

18:3-Glu elicitation and compared these transcripts with those induced by wounding. **In Manuscript II, I characterized a G-type lectin receptor-like kinase, LecRK1, identified by SuperSAGE as a putative regulatory factor of the FACs signal transduction pathway in *N. attenuata*.**

Objectives of the thesis:

- 1. Identify genes encoding for potential regulatory components of the FAC-mediated responses in *N. attenuata*.**
- 2. Characterize the role of the *N. attenuata* G-type lectin receptor-like kinase 1 gene (*NaLecRK1*) in the plant's response to *M. sexta* herbivory.**
- 3. Understand the fluxes and metabolism of C₁₂ derivatives of the HPL pathway in *N. attenuata* plants after *M. sexta* herbivory.**

SuperSAGE analysis of the *Nicotiana attenuata* transcriptome after fatty acid-amino acid elicitation (FAC): Identification of early mediators of insect responses.

Paola A. Gilardoni, Stefan Schuck, Ruth Jüngling, Björn Rotter, Ian T. Baldwin and Gustavo Bonaventure.

Published in *BMC Plant Biology* 10: 66 (2010).

In Manuscript I, we analyzed the early changes in the transcriptome of *Nicotiana attenuata* after FAC elicitation using the SuperSAGE technique combined with 454 sequencing. We identified two regulatory genes involved in insect-specific mediated responses in plants. Moreover, we provided a foundation for the identification of additional novel regulators associated with this process.

P. Gilardoni and G. Bonaventure planned and performed the experiments, analyzed the data and wrote the manuscript. S. Shuck helped to analyzed data. R. Jüngling and B. Rotter carried out experiments and analyzed the data. I.T. Baldwin participated in the design and coordination of the study and helped to draft the manuscript.

Abstract

Background: Plants trigger and tailor defense responses after perception of the oral secretions (OS) of attacking specialist lepidopteran larvae. Fatty acid-amino acid conjugates (FACs) in the OS of the *Manduca sexta* larvae are necessary and sufficient to elicit the herbivory-specific responses in *Nicotiana attenuata*, an annual wild tobacco species. How FACs are perceived and activate signal transduction mechanisms is unknown.

Results: We used SuperSAGE combined with 454 sequencing to quantify the early transcriptional changes elicited by the FAC *N*-linolenoyl-glutamic acid (18:3-Glu) and virus induced gene silencing (VIGS) to examine the function of candidate genes in the *M. sexta*-*N. attenuata* interaction. The analysis targeted mRNAs encoding regulatory components: rare transcripts with very rapid FAC-elicited kinetics (increases within 60 and declines within 120 min). From 12,744 unique Tag sequences identified (UniTags), 430 and 117 were significantly up- and down-regulated ≥ 2.5 -fold, respectively, after 18:3-Glu elicitation compared to wounding. Based on gene ontology classification, more than 25% of the annotated UniTags corresponded to putative regulatory components, including 30 transcriptional regulators and 22 protein kinases. Quantitative PCR analysis was used to analyze the FAC-dependent regulation of a subset of 27 of these UniTags and for most of them a rapid and transient induction was confirmed. Six FAC-regulated genes were functionally characterized by VIGS and two, a putative lipid phosphate phosphatase (LPP) and a protein of unknown function, were identified as important mediators of the *M. sexta*-*N. attenuata* interaction.

Conclusions: The analysis of the early changes in the transcriptome of *N. attenuata* after FAC elicitation using SuperSAGE/454 has identified regulatory genes involved in insect-specific mediated responses in plants. Moreover, it has provided a foundation for the identification of additional novel regulators associated with this process.

Background

Nicotiana attenuata is an annual native to Southwestern USA that germinates from seed banks in response to factors in wood smoke after fires [1]. Because of this germination behavior and a strong intra-specific competition, *N. attenuata* allocates resources primarily to sustain rapid growth and seed setting and as a consequence, it has developed a large number of induced defense responses to ward off the unpredictable attacks from herbivores [2]. Hence, when *N. attenuata*

is attacked by insect folivores, an extensive reprogramming of its transcriptome, proteome and metabolome takes place [3-5]. Previous studies estimated that more than 500 *N. attenuata* genes respond to *Manduca sexta* larval feeding [6] and demonstrated that the plant readjusts its metabolism for *de novo* synthesis of direct and indirect defense responses and to induce tolerance mechanisms [7-9]. Activation of these defensive mechanisms requires energy and resources from primary metabolism and involves therefore a complex rearrangement of resource allocation in the plant, including altered photosynthesis and sink/source relations [5]. How plants decode insect feeding and trigger defense and tolerance responses is starting to be understood.

For example, a SnRK1 kinase complex has been found to regulate tolerance mechanisms associated to the leaf/root partition of photoassimilates [9] and two MAPKs, WIPK and SIPK (Wound-induced and Salicylate-Induced Protein Kinases, respectively), were shown to be critical for the induction of direct defense responses in *N. attenuata* [10].

Herbivore attack induces in plants the coordinated activation of several signal cascades including those of jasmonic acid (JA), salicylic acid (SA), and ethylene (ET) [11]. Among them, JA plays a major and essential role in the induction of a large number of the plant's protective responses against insect herbivory and wounding [12,13]. Thus, having JA as a common signal, a large number of the plant responses to these two stimuli overlap, however, plants can differentiate between mechanical damage and insect herbivory to tailor their responses. The perception of components in the oral secretions (OS) of feeding larvae is one mechanism by which plants can decode insect feeding. Fatty acid-amino acid conjugates (FAC) are major components in the OS of *M. sexta* larvae and they are necessary and sufficient to induce most of the defense responses triggered by feeding *M. sexta* caterpillar in *N. attenuata* [14]. Hence, previous studies suggest the existence of central herbivore-activated regulators in *N. attenuata* leaves, which, in turn, are regulated by minute amounts of FACs in the insect's OS. Disentangling the effect of mechanical tissue damage and FAC elicitation will provide critical information on how plants control changes in its metabolism to more efficiently reduce the negative fitness consequences of herbivore attack.

One of the earliest known molecular events differentially induced by OS and FACs in tobacco is the activation of WIPK and SIPK. Activation of these protein kinases occur within the first minutes after wounding [15] and the activation is enhanced several-fold by applying *M. sexta* OS to wounds [10]. Importantly, not only their activities but also SIPK and WIPK transcript levels are rapidly (within 60 min) and transiently induced after elicitation [10,15], indicating that these regulators are under positive feedback control at the transcriptional level. One of the early targets of the FAC signal transduction pathway in *N. attenuata* is the *WRKY6* gene. Its transcript levels are also rapidly and transiently induced after wounds have been supplemented with *M. sexta* OS or synthetic FACs but only marginally by mechanical damage alone [16]. This rapid and transient kinetic of mRNA accumulation is characteristic of regulatory components and differs from that showed by, for example, transcripts encoding for defense components (e.g., protease inhibitors) which is characterized by a slower and more persistent rate of mRNA accumulation, reaching maximum levels after hours to days [8]. However, not all

regulatory components are under positive feedback control at the transcriptional level: the *Coronatine Insensitive 1 (COI1)* gene is an example in the JA transduction pathway [17]. However, some of the recently identified JAZ proteins that interact with COI1 and participate in JA-Ile perception are rapidly and transiently induced at the mRNA level by wounding in *Arabidopsis* [18].

The rapid advances in high throughput sequencing capacity in combination with new "open-architecture" techniques for quantification of gene expression has opened the possibility of performing genome-wide transcriptome studies in organisms from which massive nucleotide sequence information is not yet available. Serial analysis of gene expression (SAGE) is a technique that allows for the absolute quantification of mRNA abundance by quantifying the relative frequencies of individual short (13 nt) transcripts signatures tags [19]. Further development of the technique allowed for the generation of 26 nt tags (SuperSAGE) [20] which substantially improved the annotation of tags when aligned to sequences in public nucleotide databases [21]. With these techniques, the detection of transcripts is proportionally correlated to the scale of DNA sequencing and their combination with next generation sequencing (NGS) allows for the detection and analysis of very low abundant transcripts (frequently encoding for regulatory components) which have been estimated to account for more than 90% of mRNAs in eukaryotic cells [20,22].

Here we used SuperSAGE in combination with NGS for the quantification of the early changes (within 30 min) occurring in the transcriptome of *N. attenuata* plants after a single event of 18:3-Glu elicitation. The major objective of the study was to identify genes encoding for potential regulatory components of the FAC-mediated responses by looking for low abundant transcripts that were rapidly and transiently induced after 18:3-Glu elicitation.

Results

Generation of SuperSAGE libraries from wounded and FAC elicited *N. attenuata* leaves

Two SuperSAGE libraries were generated from the second fully expanded leaf of *N. attenuata* plants either mechanically wounded or wounded and supplemented with 18:3-Glu as a single FAC elicitor. Leaf samples were harvested after 30 min of the treatments (Figure 1). Wounding is a prerequisite for FAC-elicitation; hence, analysis of wounded leaves was used to differentiate between genes regulated by mechanical damage from those regulated more specifically or differentially by FACs. Additionally, elicitation by a single elicitor (18:3-Glu) and a single wound event were used to eliminate the effects of other OS components and repeated wounding on gene expression.

Chapter 3

The total number of SuperSAGE tags obtained after sequencing the libraries in a single 454 plate and eliminating i) incomplete reads, ii) twin-ditags, and iii) ditags without complete library-identification DNA linkers was 354,930; comprising 227,536 tags from the wounding (W) library and 127,394 from the FAC-elicited (F) library (Table 1). These tags represented 31,878 unique sequences with 19,104 (11,951 in the W library and 7,153 in the F library) detected only once (singletons) in the combined libraries, and 12,774 detected at least twice in the combined libraries (Table 1). These latter tags are referred as UniTags throughout the manuscript [22] and will be considered for further analysis. Singletons represented thus ~60% of unique sequences, in agreement with previous studies [21,22]. The complete

SuperSAGE dataset is available in Additional file 1 (see also Accession numbers).

Abundance of UniTags and annotation to public databases

The UniTags were first classified in abundance groups according to their number of copies [22]. UniTags present at ≤ 100 , $> 100 - \leq 1,000$, $> 1,000 - \leq 5,000$ and $> 5,000$ copies per million (copies.million⁻¹) were considered as low-, mid-, high- and very high-abundant tags, respectively (Table 1). The frequency distribution of the 12,774 UniTags showed that the number of copies in low and mid abundance groups ($\leq 1,000$ copies.million⁻¹) represented $> 98\%$ of the UniTags while high- and very high-abundant tags ($> 1,000$

Chapter 3

Table 1 Features of the SuperSAGE libraries from wounded and 18:3-Glu elicited leaves

Library	W**	F**	Total	(%)
Sequenced tags	227,536	127,394	354,930	(100)
Number of unique transcripts (UniTags)	11,942	10,117	12,774	
Number of singletons	11,951	7,153	19,104	
Abundance classes of UniTags*				
Very high-abundant: > 5,000 copies.million ⁻¹	24	22	46	(0.2)
High-abundant: > 1,000 - 5,000 copies.million ⁻¹	127	133	260	(1.2)
Mid-abundant: 100 - 1,000 copies.million ⁻¹	1,178	1,084	2,262	(10.2)
Low-abundant: < 100 copies.million ⁻¹	10,613	8,878	19,491	(88.4)
Total	11,942	10,117		
Copy number of Tags in Abundance classes*

Low-abundant: < 100 copies.million ⁻¹	1.98 × 10 ⁵	2.07 × 10 ⁵	4.05 × 10 ⁵	(20.2)
Total	1.00 × 10⁶	1.00 × 10⁶		

* Values normalized to 1 million tags

** W: wounded; F: 18:3-Glu elicited

copies.million⁻¹) represented only 1.4% (Table 1). However, although the latter group represented only a small fraction of the 12,774 UniTags, together they accounted for ~47% of the total number of tag copies in both the W and F libraries (Table 1). These values were in agreement with previously reported data [23,24].

Annotation of the 12,774 UniTags using basic local alignments (BLASTN) gave 5,565 tags (43.6%) that matched with a maximum of 3 mismatches (score ≥ 46.1 or e-value ≤ 6.10⁻⁴) to sequences deposited in GenBank plant nucleotide databases (Additional file 1 and Table 2). 78.8% of these 5,565 UniTags matched perfectly (26/26) with sequences in the databases while 8.4% did it with one mismatch (25/26), 6.5% with two mismatches (24/26) and 6.4% with three mismatches (23/26; Table 2). Moreover, 88% of the annotated UniTags matched sequences corresponding to *Nicotiana* spp, 5% to *Solanum* spp and 8% to other plant species (Table 2).

FAC elicitation induces differential expression of 547 UniTags

Statistically significant changes in tag copy number between the F and W libraries were analyzed by calculating a probability (*P*)-value according to [25] (see Materials and Methods for a brief description). Although small changes in expression levels may have biological significance [25], in this study we focused primarily on genes which showed strong changes in expression levels with arbitrary fold-change (FC) values ≥ 2.5 or ≤ 0.4 (FAC elicitation vs wounding). Based on the calculated (*P*)-values and using a 95% confidence level, 547 UniTags were identified as differentially expressed after FAC elicitation (Additional file 2). Among these UniTags, 430 had FC ≥ 2.5 and 117 FC ≤ 0.4 (F vs W; Figure 2a and Additional file 2). Most of the differentially expressed UniTags presented FC values between 0.2 and 10, with 29 and 24 UniTags presenting FC values ≥ 10 and ≤ 0.2, respectively (Figure 2b). The majority (98.6%) of the differentially up-regulated UniTags and all of the down-regulated UniTags corresponded to low- and mid-abundance groups (< 1,000 copies.million⁻¹; Figure 2c and Additional file 2), indicating that the strongest changes in expression levels occurred primarily in genes expressed at low to intermediate levels.

Assignment of differentially expressed UniTags to Gene Ontology (GO): biological and functional categories

To obtain gene function categories of the differentially expressed UniTags, gene ontology (GO) annotation was performed by BLASTX (using the corresponding annotated nucleotide sequences as queries) against the

Chapter 3

non-redundant GenBank and UniProtKB/TrEMBL protein databases (Additional file 2). For this analysis, we used UniTags that showed a maximum of 2 mismatches (24/26) with entries in the GenBank nucleotide database (Additional file 1). Of the 547 differentially expressed UniTags, 349 had an associated nucleotide sequence and 323 matched to an amino acid sequence entry ($e\text{-value} < 9.10^{-4}$) in the GenBank and UniProtKB/TrEMBL databases (Additional file 2). GO annotations (biological processes and/or molecular function) could be assigned to 242 of these 323 UniTags with the remaining entries corresponding to uncharacterized proteins (Additional file 2).

Among the most prevalent GO biological processes, ~25% of the UniTags classified into metabolism, ~12% into regulation of gene expression (including transcription, nucleosome assembly and mRNA processing), ~10% into amino acid phosphorylation/dephosphorylation, ~8% into translation (including ribosome assembling), ~8% into defense and stress responses, ~7% into transport, ~6% into protein degradation and folding and ~6% into signal transduction components (Figure 2d). The preponderance of changes in transcripts corresponding to metabolism, signaling, transcription, translation and transport associated processes after 30 min of

18:3-Glu elicitation emphasized the fact that at this early time point a substantial reprogramming of the leaf metabolism is already in progress. Based on changes in metabolic genes, hallmarks of this reprogramming included an increased capacity for protein synthesis and the generation of C skeletons and reducing power (see Discussion). These changes in the expression of metabolic genes are consistent with a substantial shift in primary metabolism to support secondary metabolism and tolerance mechanisms [5] and are consistent with previous gene expression studies [3,6,26] (see Discussion). The identification of regulatory factors controlling these changes in metabolism and defense and tolerance processes against insects is one of the major challenges for the future and some potential candidates are described below.

Changes in the expression of UniTags/mRNAs encoding for regulatory components

The most prevalent GO molecular function with regulatory activity corresponded to transcriptional regulators and protein kinases, represented by 30 and 22 UniTags, respectively. The protein phosphatase category contained 3 UniTags, the signal transduction category 14 UniTags and the nucleic acid binding category 6 UniTags (Additional file 2). Thus, a total of 75 annotated UniTags corresponded to factors with potential regulatory function.

Among transcriptional regulators, UniTags corresponding to WRKY transcription factors (TFs) were the most predominant (seven UniTags) and Tag-995 was the most up-regulated (23 fold) after 18:3-Glu elicitation within this group. Other UniTags for WRKYs were up-regulated between 9 and 2.5 fold (Additional file 2). Within the WRKY domain containing family, a WIZZ TF (wound-induced leucine zipper zinc finger) [27] was up-regulated 7 fold. Other prevalent up-regulated TFs included AP2-like factors (three UniTags; up-regulated between 9 and 3 fold), RAV factors (two UniTags; up-regulated ~3 fold), ethylene-responsive element binding proteins (EREBP; two UniTags; up-regulated between 9 and 3 fold) and CCR4-NOT transcription complex proteins (two UniTags; up-regulated between 7 and 3 fold) (Additional file 2). Single up-regulated UniTags in this category corresponded to a bZIP TF (2.5 fold), HIS4 (2.5 fold), S1FA (7 fold), RNA polymerase II (RNAPII; 5.5 fold) and a sigma subunit for a plastidial RNA polymerase (7 fold). Among down-regulated transcriptional regulators were a GATA-1 zinc finger protein and RNA polymerase III (RNAPIII; Additional file 2).

Within the protein kinase and phosphatase classes, three UniTags corresponded to MAPK (two up-regulated between 4 and 2.5 fold and one down-regulated 10 fold), three to cell-wall associated kinases (WAK;

up-regulated between 3.5 and 6 fold), two to BRASSINOSTEROID INSENSITIVE 1-associated receptor kinase 1 (BAK1; up-regulated between 9 and 3 fold) and three to protein phosphatase 2A (PP2A) and C (PP2C; two up-regulated ~3 fold and one down-regulated ~5-fold). In addition, this category contained a chloroplast precursor for *Arabidopsis* protein kinase 1 (APK1) [28] up-regulated ~7 fold, a shaggy-like kinase (up-regulated ~5 fold), and a cytokinin-regulated kinase 1 (CRK1; the most up-regulated, ~14 fold) and a calmodulin protein kinase 1 (up-regulated ~11 fold) among others (Additional file 2).

Within the signal transduction class, the most predominant UniTags corresponded to "Avr9/Cf-9 rapidly elicited proteins" (seven UniTags) up-regulated between 13 and 2.5 fold. Single up-regulated UniTags corresponded to a Hs1^{pro-1}-like protein (putative nematode resistance protein (NRP); 17.9 fold), SGT1 (3.6 fold), a lipid phosphate phosphatase (LPP; 5.4 fold) and an extra-large G protein (2.5 fold) were also contained in this category (Additional file 2).

Validation of the SuperSAGE data by qPCR

A subset of 27 differentially expressed UniTags (Table 3) was selected for further analysis based on the fulfillment of at least two of the following criteria: 1) strong and significant changes in their FC values (either up- or down-regulated, F vs W); 2) abundance of <1,000 copies.million⁻¹ (as regulatory components are encoded by low abundant transcripts); 3) matched known regulatory components in the databases.

The selected UniTags were first elongated by amplification of their corresponding cDNAs and BLASTed against the GenBank plant nucleotide databases to confirm their identities. All of the elongated sequences (see "Accession numbers") matched to the same entries as the original 26 bp tags (data not shown). Secondly, the elongated sequences were used to design gene-specific primers to i) validate the SuperSAGE data and ii) to study the kinetic of mRNA induction by real time quantitative PCR (qPCR). Total RNA was extracted from both wounded and 18:3-Glu elicited leaves of WT plants after different times of the stimuli.

The accumulation of 20 mRNAs corresponding to the selected UniTags was consistent with a rapid increase (within 60 min) after FAC elicitation and a rapid decrease (within 120 min) to basal or lower levels after the stimuli (Figure 3 and Additional file 3 [Figure S1]). Interestingly, several transcripts showed either no or minimal induction by wounding, representing therefore genes activated almost specifically by FACs (e.g., 837, 995, 1844, 2815; Figure 3). For some transcripts mechanical damage induced an increase in their corresponding mRNA levels which was potentiated several

¹UniTags selected for VIGS analysis are depicted in bold.

fold by 18:3-Glu elicitation (e.g., 5869, 10039; Figure 3). For transcripts corresponding to four UniTags (6032, 7036, 129, 6642), the differential regulation by 18:3-Glu elicitation could not be confirmed (Additional file 3 [Figure S1]) and they may represent false positives in the SuperSAGE analysis [25]. Finally, mRNAs for three UniTags (1439, 2452, 2990) were differentially repressed by 18:3-Glu elicitation (Additional file 3 [Figure S1]).

Functional characterization of candidate regulatory components of insect mediated responses by VIGS

To validate the use of the SuperSAGE approach for the identification of candidate regulatory components of the interaction between *N. attenuata* and *M. sexta* larvae, six genes were selected for preliminary gene function characterization by virus-induced gene silencing (VIGS). The selection of these genes was based on: 1) their kinetic of mRNA induction and 2) their fold-change compared to wounding (minimal induction by wounding -except for Tag-10039). Some of the genes encoded for putative regulatory components and two presented no

similarity to any other protein of known or predicted function (Figure 3 and Table 3). The selected UniTags corresponded to a Hs1^{pro-1}-like protein (putative nematode resistance protein (NRP); Tag-6205), lipid phosphate phosphatase (LPP; Tag-10039), *Nicotiana* elicitor induced gene (NEIG; Tag-2815), cell wall-associated protein kinase (WAK; Tag-11559), UnkA (Tag-837) and UnkB (Tag-12314) (these last two presenting no protein annotation) (Table 4). To evaluate whether these genes participate in FAC- and insect defense-mediated responses, gene-specific silenced plants and plants transformed with the empty vector (EV; control plants) were assessed for *M. sexta* larval performance and the accumulation of JA and JA-Ile after 18:3-Glu elicitation and wounding. Gene silencing efficiency in these plants was analyzed by qPCR in 18:3-Glu-elicited leaves after 1 h of the treatment (Table 4). The morphological phenotype of the silenced-plants was indistinguishable from EV control plants (data not shown).

M. sexta larva feeding on plants silenced in the expression of LPP or UnkA showed significant increases

Chapter 3

Figure 3 Analysis of mRNA accumulation corresponding to selected UniTags by qPCR. Examples of the kinetics of induction of mRNAs for 15 UniTags analyzed by qPCR after wounding and 18:3-Glu elicitation. Relative mRNA quantification was performed using the eEF1A as a reference gene for normalization and the data is expressed as fold-change relative to time 0 (unelicited leaves). Values at this time point were set arbitrary to 1. Transcripts levels were analyzed in three biological replicates ($n = 3$).

Chapter 3

Table 4 Selected genes for functional characterization by VIGS

Tag ID	Gene Name	VIGS construct	Silencing efficiency (%) ¹
Tag-6205	Nematode Resistance Protein (NRP)	pTVNRP	67 ± 1.8
Tag-10039	Lipid Phosphate Phosphatase (LPP)	pTVLPP	69 ± 2.1
Tag-11559	Wall Associated Kinase (WAK)	pTVWAK	83 ± 2.5
Tag-2815	<i>Nicotiana</i> Elicited Induced Gene (NEIG)	pTVNEIG	91 ± 5.2

Tag-12314	UnkB	pTVUNKB	98 ± 2.8

¹ The silencing efficiency is expressed as the reduction (%) of the mRNA levels in the VIGS-silenced plants relative to the levels of the corresponding mRNA in EV (empty vector) plants. In all cases the reductions were statistically significant ($P < 0.05$, t-test, EV vs VIGS).

in mass gained after 11 and/or 15 days compared to EV plants (Figure 4; see caption for statistical analysis). In contrast, larval performance was similar between EV and plants silenced in NRP, NEIG, WAK and UnkB (Additional file 3 [Figure S2]). The rate of JA and JA-Ile accumulation after wounding was similar between EV and LPP-silenced plants (Figure 5a). After 18:3-Glu elicitation, the accumulation of JA and JA-Ile was significantly slower in LPP-silenced plants however after 90 min the levels were similar to EV plants (Figure 5a, see caption for statistical analysis). Plants silenced in UnkA expression had similar rates of JA and JA-Ile accumulation to EV plants after both 18:3-Glu elicitation and wounding (Figure 5b). Likewise, induced levels of JA and JA-Ile in NRP-, WAK-, NEIG- and UnkB-silenced plants were similar to EV plants (data not shown).

Discussion

In this study we exploited the combined capacities of SuperSAGE and NGS to quantify the expression of thousands of genes in *N. attenuata* leaves elicited by one of the major elicitors (18:3-Glu) present in the OS of *M. sexta* larvae. We analyzed the expression of >335,000 SuperSAGE tags, representing 12,774 unique transcript sequences with the main objective of identifying factors with potential regulatory functions during the *M. sexta*-*N. attenuata* interaction. The analysis disclosed 75 annotated putative regulatory factors and from a subset of 27 selected we could confirm that the kinetic of mRNA induction for 20 of them followed the expected profile, a rapid and transient up-regulation.

Because the SuperSAGE generates 26 nt tags, DNA sequence databases are a prerequisite to warrant efficient gene annotation of the tags. Consistent with the presence of >17,000 *Nicotiana* spp nucleotide sequences publicly available in GenBank, ~88% of the *N. attenuata* UniTags matched to *Nicotiana* species (Table 2). However, only 43.5% of the 12,774 UniTags matched -with a maximum of 3 mismatches- to sequences in GenBank (Table 2). With a tolerance of 6 mismatches (20/26), 8,151 UniTags (64%) found a hit in this database (Additional file 1). Most SuperSAGE tags are derived from

the 3' UTR of each mRNA molecule [20] which has been shown to be allele-specific in plants [29]. Since most of the *Nicotiana* spp nucleotide entries in GenBank correspond to *N. tabacum*, a percentage of the mismatches may be attributed to polymorphisms in the 3' UTR of mRNAs from *N. attenuata* and this tobacco species. Regarding the 547 differentially expressed UniTags, 60% could be assigned to a protein entry (Additional file 2) in GenBank and UniProtKB/TrEMBL protein databases and 25% of this fraction represented fully uncharacterized protein entries (Additional file 2), a fact that partially handicapped the functional characterization of the *N. attenuata* transcription profiles. Nevertheless, a total of 242 UniTags were reliably assigned to a GO category. However, since these 242 UniTags represented < 50% of the differentially regulated mRNAs (Additional file 2), we expect that improved gene annotation will increase (probably by factor of two) the number of putative regulators that change expression after 18:3-Glu elicitation.

Changes in the expression of mRNAs encoding for regulatory components

WRKY transcription factors (TFs) occur in large gene families in plants and orchestrate different responses including those for pathogen resistance and wound healing [30,31]. For example, WRKYs bind to W-box elements in PR1 genes and regulate their expression after salicylic acid (SA) induction and pathogen elicitation [32]. WRKY3 and 6 in *N. attenuata* have been involved in responses against insect herbivores [16]. WIZZ (wound-induced leucine zipper zinc finger) was identified as an early and transiently activated wound-responsive gene in tobacco [27] and contains a leucine-zipper motif and a WRKY domain in its structure. After wounding, WIZZ transcripts accumulate within 10 min reaching maximal levels by 30 min and decreasing thereafter to basal levels [27]. Our results suggested that several WRKY members including WIZZ may play critical roles in the coordination of *M. sexta*-*N. attenuata* interactions. AP2/ERF is a large family of TFs in plants, encoding transcriptional regulators with a variety of

functions in the control of developmental and physiological processes including the integration of JA and ET signals [33]. The AP2/ERF family is classified into subfamilies containing AP2, DREB, EREBP and RAV TFs. Three AP2-like, two EREBP and two RAV TFs were rapidly up-regulated after 18:3-Glu elicitation

(Additional file 2), suggesting that this family of TF may also play important roles in the orchestration of some of the plant's responses to insect feeding.

Two UniTags corresponding to the CCR4-associated factor 1 (CAF1) were up-regulated by 18:3-Glu elicitation. CAF1 is a subunit of the CCR4-NOT complex involved in mRNA degradation and Arabidopsis plants mutated in *CAF1a* and *b* genes are more susceptible to *Pseudomonas syringae* infection [34]. These authors hypothesized that the CAF1-containing complex controls the expression of a repressor of defense genes during pathogenesis. Our results suggested that the CCR4-NOT complex may also plays a role in defense responses against insects.

Several UniTags corresponding to putative cell wall-associated protein kinases (WAKs) were rapidly up-regulated after 18:3-Glu elicitation (Additional file 2). WAKs are transmembrane proteins containing a cytoplasmic Ser/Thr kinase domain and an extracellular domain in contact with components of the plant cell walls [35]. WAKs play important roles in cell expansion, pathogen resistance, and heavy-metal stress tolerance [36,37]. These protein kinases may associate changes in the cell wall structure after insect attack with downstream responses. Indirect evidence for rapid changes in cell wall structure and metabolism comes from the substantial number of genes associated with these processes that were up-regulated after 18:3-Glu elicitation (including an arabinogalactan protein (9-fold), beta-glucan-binding protein (9-fold), cellulose synthase (6-fold), α -expansin (2.5-fold), cell wall peroxidase (7-fold), raffinose synthase (7-fold), xyloglucan endotransglycosylases (3-fold), UDP-GlcUA 4-epimerase (3-fold) and xylose isomerase (4-fold; Additional file 2). Changes in the cell wall structure trigger JA- and ET-mediated defense responses in Arabidopsis as evidenced by the *cev1* mutant, carrying a genetic lesion in a cellulose synthase gene [38]. Thus, changes in cell wall structure or homeostasis after mechanical damage and FAC elicitation might influence defensive signaling in a manner analogous to the *cev1* mutant of Arabidopsis.

GSK3/SHAGGY-like kinase is a highly conserved Ser/Thr kinase involved in several signaling pathways. The Arabidopsis BRASSINOSTEROID-INSENSITIVE 2 (BIN2) gene encodes a GSK3/SHAGGY-like kinase and was identified as a negative regulator of brassinosteroid (BR) signaling [39]. Changes in the expression of transcripts for this kinase together with BRASSINOSTEROID INSENSITIVE 1-associated receptor kinase 1 (BAK1) suggested that BR play a role in the regulation of *M. sexta*-*N. attenuata* interaction. BR induces resistance against TMV, *P. syringae* and *Oidium* spp in tobacco plants [40]. Evidence for cytokinins also playing a role in this interaction came from the strong

Chapter 3

up-regulation of the *CYTOKONIN-REGULATED KINASE 1* gene (*CRK1*) [41].

UniTags corresponding to PP2A and C were up-regulated while one UniTag corresponding to a PP2C isoform was down-regulated (Additional file 2). These regulators are known to play a central role in the control of defense-associated mechanisms. For example, the Arabidopsis AP2C1 (a PP2C) inactivates MPK4 and MPK6 and the mutant *ap2c1* produces higher amounts of JA after wounding and is more resistant to phytophagous mites than WT. In contrast, plants with increased AP2C1 activity produced less ET and had compromised immunity against necrotrophic pathogens [42].

Among components associated to signal transduction processes, genes encoding for "Avr9-Cf9 rapidly elicited proteins" were the most predominant. The GO

molecular function associated with these proteins was either protein kinase or receptor activity (Additional file 2) and some may correspond to R (resistance) genes in *N. attenuata*. The Avr9-Cf9 elicitor-receptor system is involved in the race-specific resistance of tomato (*S. lycopersicum*) against *Cladosporium fulvum* [43]. Interestingly, similar to wounding and OS elicitation, the Cf9 receptor induces the activation of WIPK and SIPK upon Avr9 binding and it has been proposed that these protein kinases are hubs in the integration of signals for diverse elicitors [44]. Thus, "Avr9/Cf9 rapidly elicited proteins" may be either important components in defense responses against insects or they may reflect redundancy (via activation of WIPK and SIPK and downstream gene expression) in the signal transduction pathway activated by wounding and FACs. An additional

regulator that shows high homology to protein kinase receptors and R genes is the putative Hs1^{pro-1}-like receptor (Additional file 2). The Hs1^{pro-1} gene confers resistance to the beet cyst nematode *Heterodera schachtii* in sugar beet (*Beta vulgaris* L.) [45]. The transcript of Hs1^{pro-1} is present at low levels in uninfected roots and it is induced specifically after nematode infection independently of SA, JA, ABA or wounding [46]. Its induction by 18:3-Glu in leaves on *N. attenuata* suggested that this gene may play a role in some plant responses against lepidopteran larvae in aboveground tissue. Up-regulation of UniTags corresponding to SGT1, a component of the Skp1-Cullin-F-box protein (SCF) ubiquitin ligases previously linked to early plant defense responses conferred by R genes [47], also suggested that signaling pathways connected to R genes may be induced by insect elicitors in *N. attenuata*.

Early changes in gene expression after 18:3-Glu elicitation reflect a rapid reprogramming of leaf metabolism

As a validation of the SuperSAGE approach, several UniTags identified as differentially regulated by 18:3-Glu elicitation corresponded to transcripts previously identified as differentially regulated by *M. sexta* larval feeding or OS/FAC elicitation [3,6,26]. Most of these genes corresponded to proteins involved in primary metabolism (Additional file 4). Changes in the expression of these genes supported the idea of a shift in primary metabolism to supply energy, C skeletons and reducing power for the synthesis of defensive compounds and to induce tolerance mechanisms [5]. Most of the putative regulatory factors identified in the present study were not identified in previous studies except for a WRKY transcription factor [26].

Changes occurring at the level of metabolism were among the most prevalent comprising more than 60 annotated UniTags. The up-regulation of twelve UniTags corresponding to transcripts for ribosomal structural proteins, four to translation initiation factors, two to tRNA synthases and several corresponding to amino acid biosynthesis (including tryptophan synthase, threonine deaminase, prephenate dehydratase and 2-isopropyl-malate synthase (Additional files 2 and 5) suggested that, within 30 min, 18:3-Glu elicitation stimulated an increased capacity for protein biosynthesis. Additionally, several annotated UniTags corresponding to genes involved in the generation of energy and C skeletons (e.g., subunits of ATP synthases, glyceraldehyde-3-phosphate-dehydrogenase, aldose-1-epimerase, fructose-bisphosphate aldolase, phosphofructokinase, sucrose synthase) and in the generation and metabolism of reducing power (e.g., NADP-dependent malic enzyme, Fed-NAD(P)⁺ reductase, NAD kinase, nicotinamidase) showed strong up-regulations (Additional file 2). NAD-

dependent malic enzymes (MEs) catalyze the oxidative decarboxylation of malate to produce pyruvate, CO₂, and NADH in mitochondria [48] while NADP-dependent plastidic and cytosolic isoforms provide C skeletons and reducing power for defense responses, lignin biosynthesis and reactive oxygen species formation [49,50]. Changes in the expression of these genes are probably necessary to meet large requirements for NADPH to supply anabolic processes.

Interestingly, several UniTags corresponding to low abundant mRNAs for isoforms of photosynthetic proteins were found up-regulated between ~3 and 7-fold, including an oxygen-evolving protein, ribulose biphosphate carboxylase activase, ribulose-1,5-bisphosphate carboxylase/oxygenase (RuBisCO) large subunit, chlorophyll a/b-binding protein, ferredoxin (Fed)-NADP(+) reductase and a PSI-H precursor (Additional files 2 and 5). In contrast to the up-regulation of these low abundant UniTags, high abundant UniTags corresponding to similar genes did not change significantly within 30 min after 18:3-Glu elicitation (e.g., Tags-4671, -3383, -1319 and -1133: photosystem II subunits; Tag-10791: light-harvesting chlorophyll a/b binding protein; Tags-11115, -11779, and -10899: RuBisCO subunits; Additional file 1). Why these low abundant isoforms of photosynthetic genes are up-regulated after elicitation is unknown. One possibility is that they play some specific roles during defense responses. In previous studies, it has been observed that after lepidopteran larvae feeding or OS/FAC elicitation transcripts encoding for photosynthetic enzymes (e.g., PSII, RuBisCO, RuBisCO activase) in attacked *N. attenuata* leaves tend to be down-regulated, with the lowest expression after several hours [6]. Long-term reductions in the synthesis of these proteins have been proposed as a mechanism that attacked plants use to reinvest resources into other processes such as the synthesis of secondary defense pathways or tolerance [5]. Within 30 min of FAC elicitation there were no significant reductions in the copy number of high abundance UniTags corresponding to mRNAs for photosynthetic proteins, suggesting that repressive mechanisms of major leaf isoforms act later during the FAC-induced response.

Identification of two mediators of *M. sexta*-*N. attenuata* interaction

The analysis of six candidate genes by VIGS identified two putative regulatory components of resistance mechanisms against lepidopteran larval feeding. Caterpillars that fed for two weeks on plants silenced in the expression of a putative lipid phosphate phosphatase (LLP) and a protein of unknown function (UnkA) gained ~2-fold and ~1.3-fold more mass, respectively, than larvae grown on EV control plants (Figure 4). Gain

of mass by the larvae can be achieved by increased foliar consumption by stimulatory mechanisms, increased efficiency of food intake by increased food quality, or a combination both [51]. By which mechanism *M. sexta* larvae grew larger on these plants is at present unknown and the subject of future investigations using stable transformed plants silenced in the expression of LPP and UnkA by RNA interference (RNAi). LPPs are signal transduction components that utilize a variety of lipid phosphate substrates including phosphatidic acid (PA), diacylglycerol pyrophosphate (DGPP), lyso-PA, ceramide 1-phosphate, and sphingosine 1-phosphate and it has been proposed that their function is to attenuate the signaling functions of these molecules [52,53].

Both LPP- and UnkA-silenced plants accumulated similar levels of JA and JA-Ile after wounding and FAC elicitation (Figure 5b), indicating that the effects of LLP and UnkA on *M. sexta* caterpillar performance was not the result of impaired JA biosynthesis. Together, these results suggested that mechanisms acting independently of JA biosynthesis must be affected in these plants to confer reduced resistance to *M. sexta* larval performance.

Conclusions

The analysis of FAC-elicited *N. attenuata* plants by combined SuperSAGE and NGS enabled the identification of multiple factors with potential regulatory activity during the *M. sexta*-*N. attenuata* interaction. Together with the use of VIGS to analyze candidate gene function we provided experimental evidence for the participation of two of these potential regulators in this interaction. The further characterization of genetically stable LLP- and UnkA-silenced plants in addition to the identification and characterization of novel regulators based on the SuperSAGE data will shed light on mechanisms used by plants to control a large reorganization of their metabolism and physiology to adjust defense and tolerance mechanisms with growth and reproduction.

Methods

Plant growth and treatments

Seeds of the 30th generation of an inbred line of *N. attenuata* plants were used as the wild-type genotype (WT) in all experiments. Plants were grown in the glasshouse at 26-30°C under 16 h of light. The second fully expanded leaf of rosette stage plants [54] were wounded by rolling a fabric pattern wheel three times on each side of the midvein and the wounds were immediately supplied with either 20 µL of 0.01% (v/v) Tween-20/water (solvent control) or 10 µL of synthetic *N*-linoleoyl-glutamic acid (18:3-Glu; 0.03 nmol/µL in 0.01% (v/v) Tween-20/water). Tissue was collected after 30 min of the treatments and frozen in liquid nitrogen for

subsequent SuperSAGE analysis. For RT-qPCR experiments, leaf samples were harvested at different time points and frozen in liquid nitrogen for subsequent RNA extraction. For VIGS experiments, plants were grown in climate chambers under 20°C, 16 h light (1000 µmol m⁻²s⁻¹) and 65% humidity. Wounding and FAC elicitation was performed as described above. Larvae of *M. sexta* were hatched overnight at 28°C and one neonate was placed on each VIGS-silenced plant (*n* = 32). The larval mass was measured using a microbalance after 4, 7, 11 and 15 days of the start of the experiment.

RNA isolation and construction of SuperSAGE libraries

Total RNA was extracted by the phenol/chloroform-LiCl method as previously described [55] and the samples were cleaned using the Plant RNA Extraction Kit (Qiagen, Hilden, Germany) following commercial instructions. poly(A)-RNA was purified from total RNA with the Oligotex mRNA mini Kit (Qiagen) according to commercial instructions. Subsequent steps for the construction of the SuperSAGE libraries and 454 sequencing were performed as previously described [21,22]. To avoid methodological artifacts and to assure the detection of true transcript variants in the libraries, double *Nla*III digestions were performed during library generation [22].

For each library, 26 bp long tags were extracted from the sequences using the GXP-Tag sorter software provided by GenXPro GmbH (Frankfurt am Main, Germany). Library comparisons were carried out using the DiscoverySpace 4.01 software [Canada's Michael Smith Genome Sciences Centre, available at <http://www.bcgsc.ca/discoveryospace>]. Statistical analysis of differentially expressed tags was calculated according to [25]. Briefly, the probability distribution represented by equation (2) in [25] was used considering *N*₁ and *N*₂ as the total number of Tags in libraries 1 and 2, respectively, and *x* as the number of copies of a given Tag in library 1 and *y* as the number of copies of the same Tag in library 2. For fold-change (FC) calculations the libraries were normalized to 100,000 tags (Additional file 1) and the FC for each tag was calculated by dividing the number of tags in the normalized FAC library (F) by the number of tags in the normalized wounded (W) library (F vs. W). Tags absent in one of the libraries (tag count = 0) were set to 1 for calculation.

Sequence homology alignments

BLAST searches were carried out using the BLASTN algorithm with the 12,774 UniTag sequences against plant nucleotide databases in GenBank (Additional file 1), filtering by selecting the *Nicotiana* (taxid: 4085) and Viridiplantae (taxid:33090) taxa. Low complexity regions were rejected and gap costs were set to 5-2. The

sequence annotation presented in Additional file 1 was restricted to hits that matched a minimum of 20 nt. UniTags that matched to < 20 nt were annotated as “no hit” in this Table. Multiple entries separated by “or” were included when the UniTag matched more than one hit with identical scores. UniTags that matched to the negative strand of the nucleotide sequence in the database carry the prefix “minus” in their respective gene identification (GI) column (Additional file 1). For protein and gene ontology (GO) annotations of differentially expressed UniTags (Additional file 2), their respective nucleotide sequences (Additional file 1) were used to perform BLASTX against the NCBI non-redundant protein database and hits with scores $< 9.10^{-4}$ were used for GO determination based on the UniProtKB/TrEMBL protein databases.

Rapid amplification of cDNA ends (3'-RACE)

For cDNA synthesis, the 3'RACE System for Rapid Amplification of cDNA Ends (Invitrogen, Karlsruhe, Germany) was used following the manufacturer's instructions and using UniTag- and gene-specific primers (Additional file 5). The PCR products were cloned into the pGEM-T easy vector (Promega, Madison, WI) and sequenced using universal primers.

Real time quantitative PCR

To analyze the mRNA levels corresponding to the 27 selected UniTags (Table 3), rosette stage *N. attenuata* WT plants were either wounded or FAC elicited as described above. Leaves were harvested at 0, 30, 60, 90, and 120 min after the treatments, total RNA extracted using the TRIzol[®] reagent (Invitrogen) and DNase-I treated (Fermentas, St. Leon-Rot, Germany). Five µg of total RNA were reverse transcribed using oligo(dT)18 and SuperScript reverse transcriptase II (Invitrogen). Quantitative real-time PCR (qPCR) was performed with a Mx3005P Multiplex qPCR system (Stratagene, La Jolla, CA) and the qPCR Core kit for SYBR[®] Green I (Eurogentec, Liege, Belgium). Relative quantification of mRNA levels was performed by the comparative ΔC_t method using the eukaryotic elongation factor 1A (NaeEF1A) mRNA as an internal standard. The sequences of the primers used for qPCR are listed in Additional file 5. All the reactions were performed with three biological replicates.

Virus induced gene silencing

Virus-induced gene silencing (VIGS) based on the tobacco rattle virus (TRV) was used to transiently silence the genes listed in Table 4 in *N. attenuata* as previously described [56]. The accession numbers

corresponding to the sequences are listed under “Accession numbers” below. Fragments of ~300 bp were amplified by PCR with the specific primers listed in Additional file 5. PCR products were digested with BamHI and SalI and inserted into plasmid pTV00 in antisense orientation. Plants transformed with the empty vector (EV) were used as control. Plants were analyzed after 15 days of leaf infiltration. Efficiency of gene silencing was evaluated by qPCR after 1 h of 18:3-Glu elicitation using the primers listed in Additional file 5.

Phytohormone extraction and quantification

For analysis of JA and JA-Ile, 0.1 g of frozen leaf material was homogenized in FastPrep[®] tubes containing 1 g of FastPrep[®] matrix (Bio101, La Jolla, CA) and 1 mL ethylacetate spiked with 0.1 µg of [9,10-²H₂]-dihydro-JA and [¹³C₆]-JA-Ile. Homogenates were centrifuged for 10 min at 4°C, the organic phase collected and plant material re-extracted with 0.5 mL ethylacetate. Organic phases were combined and the samples evaporated to dryness. The dry residue was reconstituted in 0.2 mL of 70% (v/v) methanol/water for analysis on a LC-(ESI)-MS/MS system as previously described [57].

Statistical analysis

Repeated-measurement and univariate ANOVA were calculated using SPSS v. 17.0.

Accession numbers

The SuperSAGE data was deposited in the Gene Expression Omnibus (GEO) public domain under the accession [GenBank: GSE18595]. The accession numbers for ESTs corresponding to the extended UniTag sequences are Tag-129: [GenBank: GT184388]; Tag-837: [GenBank: GT184389]; Tag-895: [GenBank: GT184390]; Tag-995: [GenBank: GT184391]; Tag-1439: [GenBank: GT184392]; Tag-1844: [GenBank: GT184393]; Tag-2067: [GenBank: GT184394]; Tag-2452: [GenBank: GT184395]; Tag-2815: [GenBank: GT184396]; Tag-2978: [GenBank: GT184397]; Tag-2990: [GenBank: GT184398]; Tag-4898: [GenBank: GT184399]; Tag-5283: [GenBank: GT184400]; Tag-5869: [GenBank: GT184401]; Tag-6032: [GenBank: GT184402]; Tag-6199: [GenBank: GT184403]; Tag-6205: [GenBank: GT184404]; Tag-6642: [GenBank: GT184405]; Tag-6938: [GenBank: GT184406]; Tag-7036: [GenBank: GT184407]; Tag-7795: [GenBank: GT184408]; Tag-9719: [GenBank: GT184409]; Tag-10039: [GenBank: GT184410]; Tag-11166: [GenBank: GT184411]; Tag-11559: [GenBank: GT184412]; Tag-12314: [GenBank: GT184413].

Figure S1. Analysis of mRNA accumulation corresponding to selected UniTags by qPCR.

Kinetics of induction of mRNAs for 12 UniTags analyzed by qPCR after wounding and 18:3-Glu elicitation. Relative mRNA quantification was performed using the eEF1A as a reference gene for normalization and the data is expressed as fold-change relative to time 0 (unelicited leaves).

Values at this time point were set arbitrary to 1. Transcripts levels were analyzed in three biological replicates ($n=3$).

Chapter 3

Figure S2. *M. sexta* larval performance on VIGS silenced plants.

N. attenuata plants were silenced in the expression of (A) NRP, (B) NEIG, (C) UnkB and (D) WAK by VIGS. Plants transformed with the empty vector (EV) were used as controls. Results are presented as the mean (\pm SE) of *M. sexta* larval mass after 4, 7, 11 and 15 days of feeding on EV and silenced plants ($n=32$ for each genotype). Statistical analysis was performed by repeated-measurement ANOVA and no significant differences were observed.

Chapter 4

ABSTRACT

Nicotiana attenuata has the capacity to respond specifically to herbivory by its natural herbivore, *Manduca sexta*, through the perception of elicitors in larval oral secretions. We demonstrate that the induction of the G-type lectin receptor kinase 1 (NaLecRK1) during *M. sexta* herbivory suppresses the larval-mediated accumulation of salicylic acid (SA) that inhibits the elicitation of critical defense molecules. Gene function analysis performed by reducing NaLecRK1 expression in *N. attenuata* by both virus induced gene silencing and inverted repeated RNA interference (ir-lecRK1 plants) revealed that NaLecRK1 was essential to mount a full defense response against *M. sexta* folivory; larvae growing on ir-lecRK1 plants were 40 to 100% larger than those growing on wild type plants. The induced accumulation of nicotine, diterpene-glucosides (DTGs), trypsin protease inhibitors (TPIs) and the expression of threonine deaminase (NaTD) were several fold reduced in ir-lecRK1 plants. The accumulation of jasmonates was unaffected during *M. sexta* herbivory in ir-lecRK1 plants however SA levels were 2-fold higher compared to wild type plants. Suppression of this enhanced SA accumulation by introgression of the *nahG* gene into ir-lecRK1 plants demonstrated that the accumulation of SA was responsible for the enhanced performance of *M. sexta* larvae and the inhibition of nicotine, DTG, TPI accumulation and NaTD expression.

Chapter 4

INTRODUCTION

Plant species from a wide taxonomical distribution trigger and tailor defense and tolerance responses against lepidopteran larval folivory after perception of components (HAEs: herbivore associated elicitors) in the oral secretions (OS) of the larvae (Tumlinson and Lait, 2005a; Schmelz et al., 2009b; Bonaventure et al., 2011b). These OS components function as chemical cues which convey sufficient information to the plant to initiate specific responses against the feeding insect (Howe and Jander, 2008a; Wu and Baldwin, 2009). Moreover, some HAEs can also counteract the defense response of plants, thus being in this case beneficial to the insect (Musser et al., 2002; Diezel et al., 2009a).

The HAEs that act during insect folivory are diverse in structure, ranging from enzymes (e.g., glucose oxidase; Musser *et al.*, 2002) to modified forms of lipids (e.g., fatty acid-amino acid conjugates (FACs); (Alborn et al., 1997b; Halitschke et al., 2001a), sulfur-containing fatty acids (caeliferins; (Alborn et al., 2007a) and from fragments of cell walls (e.g., oligogalacturonides) to peptides released from digested plant proteins (e.g., inceptins; (Schmelz et al., 2006b).

FACs belong to a widely distributed family of HAEs present in the OS of a large number of lepidopteran species including *Manduca sexta* (Yoshinaga et al., 2010a) and they are necessary and sufficient to elicit herbivory-specific responses in several plant species including maize (*Zea mays*), soybean (*Glycine max*), eggplant (*Solanum melongena*), black nightshade (*Solanum nigrum*) and wild tobacco (*Nicotiana attenuata*; (Alborn et al., 1997b; Schmelz et al., 2009b; VanDoorn et al., 2010; Bonaventure et al., 2011b). Some of the most abundant FACs are conjugates of glutamate and glutamine with unmodified or oxidized derivatives of polyunsaturated fatty acids (Alborn et al., 1997b; Spiteller and Boland, 2003; VanDoorn et al., 2010; Yoshinaga et al., 2010a). Recently, it has been demonstrated that FACs are essential for the assimilation of nitrogen by developing larvae (Yoshinaga *et al.*, 2008) making it impossible for the caterpillars to feed “stealthily” without eliciting a defense response by the plant.

Chapter 4

Nicotiana attenuata is an annual tobacco plant native to the deserts of the Southwestern USA and in its natural habitat it is frequently attacked by folivorous larvae of the specialist *M. sexta* which is frequently responsible for the majority of leaf area lost to herbivores in natural populations. In *N. attenuata*, responses to *M. sexta* herbivory and *M. sexta* OS or FAC elicitation (treatments that simulate herbivory) overlap by more than 80% and strongly differ from those induced by mechanical damage (Halitschke *et al.*, 2001). These responses include among others changes in the expression of more than 500 genes, 90 proteins, 170 metabolites and the differential production of jasmonic acid (JA), ethylene (ET) and salicylic acid (SA; Hermsmeier *et al.*, 2001; Giri *et al.*, 2006; Gilardoni *et al.*, 2010; Gaquerel *et al.*, 2010; Kallenbach *et al.*, 2010).

The biosynthesis of JA and jasmonyl-Isoleucine (JA-Ile) and their perception are essential for the triggering of induced defense responses to chewing arthropods in different plant species (Staswick and Tiryaki, 2004; Wang *et al.*, 2007; Howe and Jander, 2008; Vandoorn *et al.*, 2011). In *N. attenuata* plants, critical defense responses which are induced during *M. sexta* folivory include the accumulation of the defense metabolites 17-hydroxygeranyllinalool diterpene glycosides (HGL-DTGs), nicotine, phenylpropanoid-polyamine conjugates and protease inhibitors (PIs); when *N. attenuata* plants are engineered to produce reduced amounts of these molecules they become severely compromised in their capacity to survive *M. sexta* attack (Steppuhn *et al.*, 2004; Zavala *et al.*, 2004; Jassbi *et al.*, 2008; Kaur *et al.*, 2010). In tomato (*Solanum lycopersicum*) and *N. attenuata*, the induction of threonine deaminase (TD) is also a critical induced defense response. TD participates in the deamination of threonine (Thr) to form α -ketobutyrate for isoleucine (Ile) biosynthesis and in *N. attenuata* reduced *NaTD* expression compromises the levels of JA-Ile formation in leaves and thereby the induction of defense responses such as nicotine and trypsin protease inhibitor (TPI) accumulation (Kang *et al.*, 2006b). In tomato, an active form of SITD2 lacking its regulatory domain deaminates Thr in the gut of *M. sexta* larvae and thereby reduces the ingested levels of this essential amino acid for larval growth (Chen *et al.*, 2005).

Although JA plays a prominent role in the induction of defense responses against chewing insects in plants, salicylic acid (SA) and ethylene (ET) can modulate either

Chapter 4

positively or negatively the induction of defense responses stimulated by JA (Doherty *et al.*, 1988; Doares *et al.*, 1995; O'Donnell *et al.*, 1996; Stotz *et al.*, 2002; Zarate *et al.*, 2007; Diezel *et al.*, 2009) and the antagonistic and synergistic effects between JA, SA and ET signaling pathways have been extensively documented (Niki *et al.*, 1998; Reymond and Farmer, 1998; Gupta *et al.*, 2000; Li *et al.*, 2004; Mur *et al.*, 2006; Leon-Reyes *et al.*, 2009; Diezel *et al.*, 2009). Importantly, the stimulatory effect of JA and the modulation of the JA-mediated responses by SA and ET are the major known determinants of the final response triggered by plants during their interaction with lepidopteran larvae (Howe and Jander, 2008). Also important is the fact that the level of production of JA, SA and ET in plants depends on the attacking herbivore and thereby both plants and insects try to adjust or prevent, respectively, the induction of defense responses (Musser *et al.*, 2006; Howe and Jander, 2008; Diezel *et al.*, 2009).

At present, little is known about the signal transduction components operating specifically during insect herbivory and controlling the modulation of induced defense responses in plants during this biotic stress. Among the known signal components acting early upon wounding and recognition of FACs or *M. sexta* OS in *N. tabacum* and *N. attenuata* plants are two mitogen-activated protein kinases (MAPKs), WIPK (wound-induced protein kinase) and SIPK (salicylate-induced protein kinase; (Seo *et al.*, 1999; Wu *et al.*, 2007). In *N. attenuata*, NaSIPK and NaWIPK affect JA biosynthesis (Kallenbach *et al.*, 2010) and a large number of induced defense responses (Wu *et al.*, 2007) and in *N. tabacum* they affect JA and SA accumulation after wounding (Seo *et al.*, 2007). In tomato, the protein kinase 1b (TPK1b) and the MAPKs LeMPK1, LeMPK2 and LeMPK3 play important roles in mediating JA- and ET-dependent defense responses against folivorous insects (Kandoth *et al.*, 2007; AbuQamar *et al.*, 2008).

With the aim of identifying additional signal transduction components of the pathways controlling defense and tolerance responses against lepidopteran larvae, a SuperSAGE (serial analysis of gene expression) approach combined with 454 sequencing was recently used to quantify the early transcriptional changes elicited by the FAC *N*-linolenoyl-glutamic acid (18:3-Glu) in *N. attenuata* plants (Gilardoni *et al.*, 2010). The analysis targeted mRNAs encoding regulatory components: rare transcripts with very rapid

Chapter 4

FAC-elicited kinetics. From 12,744 unique tag sequences identified (UniTags), the abundance of 430 and 117 were significantly increased and decreased, respectively, in the SuperSAGE library corresponding to 18:3-Glu-elicited leaves compared to that corresponding to wounded leaves. More than 25% of the UniTag sequences matched to putative regulatory components including 22 protein kinases (Gilardoni *et al.*, 2010). Here we demonstrate that the OS/FAC-mediated induction of the *N. attenuata* G-type lectin receptor kinase 1 (NaLecRK1) is essential during *M. sexta* larval herbivory to suppress the accumulation of SA and thereby indispensable to stimulate the unfettered JA-mediated induction of critical defense metabolites in *N. attenuata*.

RESULTS

Identification of NaLecRK1 as a regulator of the interaction between *N. attenuata* and *M. sexta*

From the SuperSAGE analysis published recently by Gilardoni *et al* (2010), the UniTag-5358 was identified as a tag whose abundance was 11-fold enriched in the SuperSAGE library corresponding to 18:3-Glu elicited leaves compared to the library corresponding to wounded leaves. To unravel the role of the gene corresponding to UniTag-5358, we first obtained the full length cDNA of this Unitag by 5' and 3' random amplification of cDNA ends (RACE). The full length cDNA nucleotide sequence contained an open reading frame (ORF) of ~2.5 kb encoding for a predicted polypeptide of 833 amino acids (see GenBank accession number in Materials and Methods). Analysis of sequence similarity by basic local alignment (BLAST) using the complete predicted amino acid sequence of UniTag-5358 showed that the protein sequence presented on average more than 80% sequence similarity to receptor-like kinases of the lectin domain superfamily (Supplemental Figure S1 online; (Bouwmeester and Govers, 2009). The closest homologues to NaLecRK1 with known functions were the lectin receptor kinase protein NbLRK1 from *Nicotiana benthamiana* (Kanzaki *et al.*, 2008), Pi-d2 from rice (*Oryza sativa*; Chen *et al.*, 2006) and NgRLK1 from *Nicotiana glutinosa* (Kim *et al.*, 2010; Supplemental

Chapter 4

Figure S1 online); the function of these genes has been associated to defense responses against microbial pathogens.

The amino acid sequence of UniTag-5358 contains a predicted N-terminal extracellular region, a single transmembrane spanning α -helix and a C-terminal cytoplasmic region (Figure 1A). The extracellular N-terminal region contains a predicted 22 amino acid signal sequence to the secretory pathway (amino acids 1 to 22), a lectin domain from amino acids 55 to 177 (e-value $4.08e^{-16}$; SMART algorithm (Letunic *et al.*, 2009)), an epidermal growth factor-like domain (EGF) from amino acids 310 to 364 (e-value $6.51e^{-02}$) and a PAN_AP (plasminogen-apple-nematode motif) domain from amino acids 364 to 445 (e-value $1.47e^{-02}$; Figure 1A). The predicted transmembrane domain expands from amino acids 476 to 490 (e-value $9.9e^{-02}$) and the C-terminal cytoplasmic region contains a predicted Ser/Thr kinase domain from amino acids 519 to 788 (e-value $9.04e^{-31}$; Figure 1A and Supplemental Figure S1 online).

In Arabidopsis, lectin receptor kinases (LecRKs) are divided in three classes based on the type of extracellular lectin domain: G-, C- and L-type LecRKs (Bouwmeester and Govers, 2009). The G-type LecRKs present a G-type lectin motif, one EGF and PAN_AP domains in the N-terminal region (Bouwmeester and Govers, 2009); domains that were present in UniTag-5358 (Figure 1A and Supplemental Figure S1 online). The gene corresponding to UniTag-5358 was therefore renamed *NaLecRK1* (*N. attenuata* G-type lectin receptor kinase 1).

SIPK and WIPK are positive regulators of NaLecRK1 expression while jasmonates have an inhibitory role

The kinetic of *NaLecRK1* mRNA induction in leaves as a response to OS elicitation (from *M. sexta*, *S. littoralis* and *Schistocera gregaria* (grasshopper)), 18:3-Glu elicitation and wounding was first evaluated in *N. attenuata* wild type (WT) plants. Consistent with the SuperSAGE data (Gilardoni *et al.*, 2010), *NaLecRK1* transcript levels were strongly increased (ca. 60-fold) at 1 h after 18:3-Glu elicitation (compared to basal transcript levels in unelicited leaves; Figure 1B). Moreover, the increase was transient and *NaLecRK1*

Chapter 4

mRNA levels decreased rapidly (within 2 h) to basal levels (Figure 1B). In wounded leaves, *NaLecRK1* mRNA levels were also increased (ca. 7-fold) at 1 h (Figure 1B) showing that mechanical damage also induces the expression of this gene however to levels lower than 18:3-Glu elicitation. Elicitation with *M. sexta* OS induced a 100-fold increase in *NaLecRK1* transcript levels and elicitation with *S. littoralis* OS induced a 50-fold increase (compared to basal levels; Figure 1B). In contrast, elicitation with *S. gregaria* OS showed an effect similar to wounding (Figure 1B), a result consistent with undetectable levels of FACs in the *S. gregaria* OS (Schafer et al., 2011).

Second, we asked whether the induction of *NaLecRK1* expression depended on NaSIPK and NaWIPK activities (these MAPKs control the earliest known molecular events that trigger defense responses against *M. sexta* herbivory; Wu *et al.*, 2007). Plants with reduced expression of these two genes (*ir-sipk* and *ir-wipk*, respectively; Wu *et al.*, 2007) were elicited with 18:3-Glu and the *NaLecRK1* mRNA levels were analyzed. The induction of this transcript was delayed and reduced by approximately 2-fold in *ir-sipk* plants compared to WT whereas completely absent in *ir-wipk* plants (Figure 1C).

Third, to evaluate whether the induction of *NaLecRK1* mRNA levels was dependent on the endogenous production of JA and JA-Ile, plants with reduced expression of *LIPOXYGENASE 3* (*NaLOX3*) and *CORONATIVE INSENSITIVE 1* (*NaCOI1*) genes were elicited with 18:3-Glu. These plants, *ir-lox3* and *ir-coi1*, are deficient in JA accumulation (Allmann *et al.*, 2010) and JA signaling (Paschold et al., 2008), respectively. In contrast to *ir-sipk* and *ir-wipk* plants, the induction of *NaLecRK1* transcript levels in *ir-lox3* and *ir-coi1* plants was accelerated and increased to levels 3 fold higher than in WT plants (Figure 1C). Together, these results indicated that, after 18:3-Glu elicitation, NaSIPK and NaWIPK are positive regulators of *NaLecRK1* gene expression whereas jasmonates have an inhibitory effect.

Finally, the tissue specific expression of *NaLecRK1* was studied and based on the accumulation of transcript levels, *NaLecRK1* was expressed ubiquitously in all tissues analyzed with higher levels of expression in roots and stems compared to rosette leaves and flower parts (Figure 1D).

Chapter 4

Figure 1. NaLecRK1 predicted domains and mRNA expression pattern.

(A) Schematic representation of NaLecRK1 domain composition and organization based on conserved domain analysis. PAN_AP, plasminogen-apple-nematode motif; EGF, epidermal growth factor-like motif; Ser/Thr: serine/threonine protein kinase domain.

(B) Leaves of rosette stage wild-type (WT) *N. attenuata* plants were either wounded or elicited with OS collected from different insects or synthetic FAC (18:3-Glu). The NaLecRK1 mRNA levels were quantified by qPCR and values are expressed as the fold-change (FC) increase relative to time 0 (value set arbitrary at 1). The NaLecRK1 mRNA levels were calculated relative to the expression level of NaEF1A mRNA using the ΔCT method; see Materials and Methods). *: $P < 0.05$, Student's t-test, (wounding vs. elicitation at same time point, bars denote $\pm\text{SE}$, $n=3$).

(C) Leaves of rosette stage wild-type (WT) and different *ir*-silenced *N. attenuata* plants were elicited with synthetic FAC (18:3-Glu). The NaLecRK1 mRNA levels were analyzed as in (B). *: $P < 0.05$, Student's t-test (WT vs. *ir*-silenced plants at same time point, bars denote $\pm\text{SE}$, $n=3$).

(D) NaLecRK1 mRNA levels were quantified by qPCR as described in (B) in different tissues of rosette stage and early flowering *N. attenuata* WT plants. Bars denote $\pm\text{SE}$ ($n=3$). Different letters indicate significant differences (univariate ANOVA, $F_{8,25} = 17.38$, $P < 0.001$, followed by a Tukey HSD post-hoc test, $P < 0.05$).

Chapter 4

Silencing of *NaLecRK1* expression transiently by VIGS and stably by inverted-repeat RNAi reveals a critical function of this gene in *N. attenuata* defense responses against *M. sexta* folivory

The function of *NaLecRK1* in the response of *N. attenuata* to *M. sexta* herbivory was first evaluated by transiently reducing the expression of the *NaLecRK1* gene by virus-induced gene silencing (VIGS). An 86 bp fragment corresponding to the 3'-UTR of the *NaLecRK1* mRNA was used to reduce its expression by the tobacco rattle virus (TRV) system (Ratcliff *et al.*, 2001) and *Agrobacterium tumefaciens* leaf infiltration (Saedler and Baldwin, 2004). Fifteen days after leaf infiltration, the *NaLecRK1* mRNA levels were analyzed in newly emerged leaves of plants infected to reduce *NaLecRK1* expression (*NaLecRK1*-VIGS) and control plants infected with the empty vector (EV-VIGS). *NaLecRK1* transcript levels were reduced between 85% and 90% after both wounding and 18:3-Glu elicitation in *NaLecRK1*-VIGS plants compared to EV-VIGS plants (Supplemental Figure S2A online).

Second, freshly hatched *M. sexta* neonates were placed on these plants and the larval masses were determined at 4, 7 and 11 days after the start of the experiment. Larvae feeding on *NaLecRK1*-VIGS plants gained ca. 50% and 100% more mass after 7 and 11 days, respectively, compared to larvae feeding on EV-VIGS plants (Supplemental Figure S2B online). These results suggested that *NaLecRK1* plays an important role in the control of the interaction between *N. attenuata* and *M. sexta*.

To examine in further detail the function of *NaLecRK1*, stably transformed *N. attenuata* plants with reduced expression of *NaLecRK1* were generated by inverted repeat-mediated RNA interference (IR-RNAi; see Materials and Methods for a detailed description of the generation of these plants). Two homozygous independently transformed lines (A-08-378-5-4-1 and A-08-380-6-3-8) named *ir-lecRK1-378* and *ir-lecRK1-380*, respectively, were selected and used for all the experiments described below (Figure 2). These lines carried a single T-DNA insertion in their genomes (Figure 2A) and the levels of *NaLecRK1* mRNA were reduced on average by 95% compared to WT plants after 18:3-Glu elicitation (Figure 2B). The growth and morphology of *ir-lecRK1* plants were indistinguishable from those of WT plants at all stages of development (Figure 2C).

Chapter 4

Figure 2. Silencing efficiency in ir-lecRK1 plants and growth morphology.

(A) Southern blot analysis of two independently transformed ir-lecRK1 lines (ir-lecRK1-378 and ir-lecRK1-380). Genomic DNA from ir-lecRK1-378, ir-lecRK1-380 and WT plants was digested with *EcoRV* and analyzed as described in Materials and Methods. Both ir-lecRK1 lines harbored a single T-DNA insertion (arrow head).

(B) Mean (\pm SE) of transcripts levels of *NaLecRK1* in leaves 1 h after *M. sexta* OS elicitation ($n=3$). *NaLecRK1* mRNA levels were quantified as described in caption of Figure 1B. *: $P < 0.05$, Student's t-test (WT vs. ir-lecRK1 plants).

(C) Morphology of WT and ir-lecRK1 plants in rosette stage (left) and mature (elongated) plants (right).

Chapter 4

To confirm the results observed with NaLecRK1-VIGS plants, freshly hatched *M. sexta* larvae were placed on WT, ir-lecRK1-378 and ir-lecRK1-380 plants and the mass of the larvae were determined at 4, 7 and 11 days after the start of the experiment. Larvae growing on ir-lecRK1 plants gained 30% to 35% more mass after 11 days of feeding than larvae growing on WT plants (Figures 3A and 3B). Estimation of the leaf area consumed after 11 days showed that ir-lecRK1 plants lost on average 2 times the leaf area of WT plants (inset Figure 3A). The levels of total protein and starch in leaves were similar between ir-lecRK1 and WT plants (Supplemental Figure S3 online). In conclusion, the stable reduction of NaLecRK1 expression in transgenic plants was consistent with the function of this gene in the regulation of defense responses in *N. attenuata* against *M. sexta* herbivory.

Reduction of NaLecRK1 expression increases the accumulation of SA after simulated herbivory

To evaluate whether the reduced expression of NaLecRK1 affected the production of JA, JA-Ile, SA and ET, the levels of these phytohormones were quantified in ir-lecRK1 and WT plants at different times after wounding and *M. sexta* OS elicitation. The accumulation of JA was similar between WT and ir-lecRK1 plants after both treatments (Figure 3C and Supplemental Figure S4A online). In contrast, 1 h after OS elicitation, JA-Ile levels were reduced by 34% and 26% in ir-lecRK1-378 and ir-lecRK1-380 plants, respectively, compared to WT plants (Figure 3D). At 1 and 3 h after wounding, the levels of JA-Ile were similar between WT and ir-lecRK1 plants (Supplemental Figure S4B online). Interestingly, 3 h after OS elicitation, the levels of SA were increased by 2- and 2.5-fold in ir-lecRK1-378 and ir-lecRK1-380 plants, respectively, remaining 1.4-fold higher at 4 h compared to WT plants (Figure 3E). After wounding, the SA levels were similar between WT plants and ir-lecRK1 plants (Supplemental Figure S4C online). Finally, the levels of ET produced by WT and ir-lecRK1 plants after OS elicitation and wounding were also similar (Supplemental Figure S5 online).

Figure 3. *ir-lecRK1* plants are more susceptible to *Manduca sexta* herbivory.

(A) Mean (\pm SE) of *M. sexta* larval mass after 4, 7 and 11 days of feeding on WT plants and two *ir-lecRK1* lines (378 and 380). Statistical analysis was performed by repeated-measurement ANOVA ($F_{1,87} = 5.25$, $P < 0.01$, $n=30$), asterisks indicate significant differences between larvae feeding on WT plants and those feeding on *ir-lecRK1* plants. The insert shows the estimation of the leaf area consumed by *M. sexta* larvae after 11 days of feeding ($n=20$ leaves obtained from 20 individual plants per genotype). *: $P < 0.05$, Student's t-test (WT vs. *ir-lecRK1* plants).

(B) Example of *M. sexta* larvae at 11 days after feeding on WT or on *ir-lecRK1* plants.

(C) JA levels in WT and *ir-lecRK1* plants. Leaves from WT and *ir-lecRK1* plants were elicited with *M. sexta* OS and leaf tissue was harvested at different times after the treatments for JA quantification by LC-MS/MS.

(D) JA-Ile levels analyzed as in (C). *: $P < 0.05$, Student's t-test (WT vs. genotype at the same time point), bars denote \pm SE, $n=4$.

(E) SA levels analyzed as in (C). *: $P < 0.05$, Student's t-test (WT vs. genotype at the same time point), bars denote \pm SE, $n=4$.

Chapter 4

Metabolic profiling of ir-lecRK1 plants reveals strong changes in the accumulation of defense metabolites

Because defense responses of *N. attenuata* against *M. sexta* herbivory rely strongly on the *de novo* synthesis of defense metabolites and thereby on changes in primary and secondary metabolism, the differential accumulation of metabolites in OS-elicited leaves from ir-lecRK1 and WT plants was profiled by LC-ToF-MS (liquid chromatography time-of-flight mass spectrometry) analysis. OS-elicited leaves were harvested at 12 h and 3 and 6 days after the treatment and polar metabolites were analyzed using a modified version of a previously described LC-ToF-MS method (Gaquerel et al., 2010) (see Material and Methods for a detailed description of the method used). Positively charged metabolites were selected using the ESI (electrospray ionization) interface in the positive ion mode and those metabolites eluting from the column between 125 and 550 sec and having *m/z* values ranging from 90 to 1400 were selected for analysis (see Material and Methods for a detailed description of the analysis). By using the conditions mentioned above and after data processing, a total of 2,831 ions were identified (Supplemental Table S1 online). To identify the ions that accumulated differentially in WT and ir-lecRK1-378 plants, the fold-changes in ion abundance between these two genotypes were calculated. Ion abundances that differed statistically (*P*-value ≤ 0.05) and had fold-changes larger than 1.5 and smaller than 0.67 (ir-lecRK1-378 vs WT) were considered as up- and down-regulated, respectively. Although this selection was arbitrary, it has proved useful for the identification of differentially regulated metabolites in *N. attenuata* plants during *M. sexta* herbivory (Gaquerel et al., 2010). Using these conditions, a total of 148 ions accumulated differentially after OS elicitation in ir-lecRK1-378 versus WT plants with 57 up- and 91 down-regulated (Supplemental Table S2 online). Most of these ions accumulated specifically at particular times with only 7 ions accumulating differentially after both 12 h and 3 days of the treatment and 2 ions after both 12 h and 6 d after the treatment (Figure 4A).

To facilitate the graphical interpretation of the differences among genotypes and times of treatments, the data set corresponding to the differentially accumulating ions was first analyzed by Principal Component Analysis (PCA). The first and second principal

Chapter 4

components (PC) together explained 64.7% of the variation within this data set and PC1 and 2 clearly separated the samples based on genotype and times of the treatments (Supplemental Figure S6A online). A supervised method, PLSDA (Partial Least Squares Discriminant Analysis), was then used to help with the identification of those ions with stronger effects on the separation of samples. The first and second principal components (PCs) of the PLSDA analysis explained 62.4% of the variation in the data set and, similar to PCA analysis, these two PCs clearly separated ir-lecRK1-378 samples from WT samples at the different times of the experiment (Figure 4B). The PLSDA analysis was validated by a permutation test as previously described (Westerhuis *et al.*, 2008; Supplemental Figure S6B online) and was used to calculate the VIP (variable importance in the projection) value to estimate and rank the influence of individual ions on the separation of the samples by the PLSDA model. VIP values equal to or larger than 1.0 were considered significant and the higher the VIP value was, the stronger was its influence on the separation of the samples (Xie *et al.*, 2008; Qiu *et al.*, 2009). A total of 42 ions presented VIP values larger or equal to 1.0 and 16 of these ions were down- and 26 up-regulated at specific times (Supplemental Table S3 online). The fold change in the abundance of these 42 ions ranged from 0.0025 to 0.67 for the down-regulated ions and from 1.5 to 146 for the up-regulated ions (ir-lecRK1 vs WT; Supplemental Table S3 online).

To define the identity of the 148 differentially accumulating ions, a search in the public metabolite database and in custom databases (Gaquerel *et al.*, 2010; Heiling *et al.*, 2010)) was performed using the *m/z* values (with an error of ± 0.02) and the retention times. Approximately 87% of the ions did not match significantly to any of the metabolites in the databases and for some of these metabolites a theoretical elemental molecular formula could be assigned with a significant degree of confidence (Table 1 and Supplemental Tables S2 and S3 online). Importantly, among the identified metabolites, were several involved in defense responses against *M. sexta* herbivory. Different ions corresponding to nicotine and HGL-DTGs were found significantly down-regulated at different times after OS elicitation in ir-lecRK1-378 compared to WT plants (Table 1). *N. attenuata* accumulates 11 different HGL-DTG forms differing from each other in the sugar moiety they carry and in the number of malonyl ester groups in the sugar moieties (Heiling *et al.*, 2010). Among the 11 HGL-DTG forms, Lyciumoside IV and Attenoside were reduced in ir-lecRK1-378 at 12 h

Chapter 4

and 3 days after OS elicitation while the monomalonylated HGL-DTGs Nicotianoside I, Nicotianoside IV and Nicotianoside VI and the dimalonylated HGL-DTGs Nicotianoside II were reduced at 6 days after the treatment (Table 1 and Supplemental Table S2 online). Nicotine and Nicotianoside II were among the metabolites with VIPs greater or equal to 1.0 (Figure 4C and Supplemental Table S3 online), indicating that they strongly contributed to the separation of samples observed in the PLSDA analysis (Figure 4B).

Figure 4. Leaf metabolic profiling of ir-lecRK1 and WT plants.

Leaves from rosette stage WT and ir-lecRK1-378 plants were elicited with *M. sexta* OS and leaf tissue was harvested at 0.5, 3 and 6 days after the treatment. After extraction, polar metabolites were analyzed by UPLC-ToF-MS in the positive ion mode of the ESI.

(A) Venn-diagram depicting the number of statistically up (↑) and down (↓) regulated ions in ir-lecRK1-378 vs. WT plants (P -values < 0.05 and fold-changes (FC) ≤ 0.7 and ≥ 1.5) at different times after the treatments (see also Supplemental Table S2 online).

(B) PLSDA analysis of the down and up-regulated ions in ir-lecRK1-378 vs. WT. Principal components 1 and 2 explained together 62.4% of the variance of the samples (the explained variances per component are shown in brackets). Ellipses delimit the 95% statistical confidence areas for each biological group in the score plots.

(C) Ranking of ions presenting VIP (Variance Importance in Projection) score values bigger than 1.0 in the separation of samples by PLSDA (B). The bigger the VIP score the bigger the ranking value (y-axis; see Supplemental Table S3 online) and the stronger the influence of the ion. The numbers next to the dots describe the reference number for the specific ion (Supplemental Table S1 online).

Chapter 4

NaLecRK1 expression affects the *M. sexta* OS-mediated induction of nicotine and HGL-DTG levels

Previous studies have shown that *M. sexta* larvae fed on *N. attenuata* plants with reduced levels of nicotine or HGL-DTGs gained several fold more mass than larvae fed on WT plants (Steppuhn *et al.*, 2004; Jassbi *et al.*, 2008). Based on the reductions in nicotine and HGL-DTGs levels detected in ir-lecRK1-378 plants by metabolic profiling, nicotine and total HGL-DTGs were quantified by HPLC in WT and the two ir-lecRK1 lines (378 and 380) at different times after wounding or *M. sexta* OS elicitation. The nicotine levels in unelicited and wounded leaves were similar between WT and ir-lecRK1 plants (Figure 5A and Supplemental Figure S7A online). In contrast, at 3 and 6 days after OS elicitation, the induced nicotine levels in ir-lecRK1-378 and ir-lecRK1-380 plants were on average 30% and 40% reduced, respectively, compared to WT plants (Figure 5A).

In unelicited and wounded leaves, total HGL-DTG levels were similar between WT and ir-lecRK1 plants (Figure 5B and Supplemental Figure S7B online) however the levels of induced HGL-DTGs were reduced on average by 60% and 40% at 3 and 6 days, respectively, after OS elicitation in ir-lecRK1 plants compared to WT plants (Figure 5B). Analysis of the different forms of HGL-DTGs revealed that the amounts of the precursor molecules Lyciumoside I and Lyciumoside II were similar between WT and ir-lecRK1-378 plants at the different times of the experiment, however, the core molecules Lyciumoside IV (the most abundant HGL-DTG form) and Nicotianoside III were reduced by 32% and 43%, respectively, at 3 days after the treatment in ir-lecRK1 plants compared to WT plants (Figures 5C and 5D). At day 6 after the treatment, the reduction in Lyciumoside IV amounts was of 60% (Figure 5D). The levels of the monomalonylated HGL-DTGs Nicotianoside and Nicotianoside IV were reduced by 70% and Nicotianoside VI by 24% in ir-lecRK1 plants compared to WT plants at 6 days after OS elicitation (Figure 5D). The levels of the dimalonylated HGL-DTGs Nicotianoside II, Nicotianoside V and Nicotianoside VII were reduced by 85%, 86% and 78%, respectively, in ir-lecRK1 plants compared to WT plants at 6 days after the treatment (Figure 5D). In summary, the accumulation of most of the core and mono and dimalonylated forms of HGL-DTG molecules was reduced in ir-lecRK1 plants after *M. sexta* OS elicitation.

Chapter 4

The transcript levels of the plastidial geranylgeranyl pyrophosphate synthase (NaGGPPS), the enzyme involved in the biosynthesis of HGL-DTGs (Jassbi *et al.*, 2008), were reduced by 2 fold in leaves of *ir-lecRK1* compared to WT plants at 24 and 72 h after OS elicitation (Supplemental Figure S8A online), suggesting that NaLecRK1 affects (at least partially) the induced levels of HGL-DTGs by affecting the expression of the biosynthetic enzyme NaGGPPS.

The phenyl-propanoid-polyamine conjugates caffeoylputrescine (CP) and dicaffeoylspermidine (DCS) and the phenyl-propanoid derivatives chlorogenic acid (CGA) and rutin are metabolites whose accumulation has been associated with defense against *M. sexta* herbivory in *N. attenuata* (Kaur *et al.*, 2010). The amounts of these four metabolites were quantified in *ir-lecRK1* and WT plants at 3 days after both wounding and *M. sexta* OS elicitation and their levels did not differ between WT and *ir-lecRK1* plants (Supplemental Figure S9 online). These results were consistent with the metabolic profiling analysis that showed no significant differences in the accumulation of these metabolites (Supplemental Table S1 online) and indicated that NaLecRK1 specifically affects the accumulation of some defense metabolites in *N. attenuata*.

(D) Mean (\pm SE) of individual HGL-DTGs quantified by LC-MS/MS. In this case, leaf tissue was harvested at 0, 0.5, 1, 3 and 6 days after *M. sexta* OS elicitation. The amounts of individual HGL-DTGs were normalized by gram fresh mass and to the peak area of the internal standard glycyrrhizinic acid. * $P \leq 0.05$, ** $P \leq 0.01$ and *** $P \leq 0.001$, Student's t-test (WT vs. *ir-lecRK1-378* at same time point, $n=4$).

NaLecRK1 expression affects the *M. sexta* OS-mediated induction of TPI activity

Trypsin protease inhibitors (TPIs) are induced during *M. sexta* herbivory in *N. attenuata* plants and they play a critical role as direct defenses by inhibiting the hydrolysis of ingested proteins in the digestive system of *M. sexta* larvae; *N. attenuata* plants with reduced expression of NaTPI are compromised in their defense against *M. sexta* herbivory (Zavala *et al.*, 2004a). To evaluate whether NaLecRK1 affected the levels of TPI activity, leaves from WT and *ir-lecRK1* plants were elicited with *M. sexta* OS and TPI activity was quantified at 2 and 3 days after the treatment. In unelicited leaves, TPI activity was similar between WT and *ir-lecRK1* plants (Figure 6) and the induced levels did not differ between genotypes after wounding (Supplemental Figure S7C online). In contrast, after OS elicitation, the induced TPI activity was reduced by 40% in *ir-lecRK1* plants compared to WT (Figure 6). In agreement, the induction of NaTPI transcript levels was reduced by ca. 50% in *ir-lecRK1-378* plants compared to WT plants at 24 h after OS elicitation (Supplemental Figure S8B online). Thus, not only nicotine and HGL-DTGs were induced to lower levels than in WT in *ir-lecRK1* plants but also TPI expression and activity, indicating that, although NaLecRK1 affects the specific accumulation of some defense metabolites, it may have a broader effect on the induction of defense responses against herbivores.

Figure 6. ir-lecRK1 plants induce reduced levels of trypsin proteinase inhibitors (TPI). Leaves from rosette stage WT and ir-lecRK1 plants were elicited with *M. sexta* OS. After 2 and 3 days of the treatments, leaf tissue was harvested and analyzed for TPI activity by a radial diffusion assay. Basal levels are from uninduced leaves. *: $P < 0.05$, Student's t-test (WT vs. ir-lecRK1 at the same time point), bars denote \pm SE, $n=4$.

The expression of *NaTD* is strongly reduced in leaves of ir-lecRK1 plants after OS elicitation

To gain further insights into the mechanisms affected in ir-lecRK1 plants, changes in gene expression at 1 h after *M. sexta* OS elicitation were evaluated by microarray analysis. Differentially regulated genes were considered when $\log_2(\text{fold-changes; FCs})$ were larger or equal to 1.3 or smaller or equal to -1.3 (ir-lecRK1-378 vs. WT) and q-values were lower than 0.05 (corresponding to a 4% false discovery rate (FDR); see Materials and Methods). Using these conditions, transcripts corresponding to 78 genes were identified as differentially regulated in ir-lecRK1-378 compared to WT, with 41 down- and 37 up-regulated (Supplemental Table S4 online). Thirty of these 78 genes did not match

Chapter 4

significantly with any of the protein entries in the non-redundant (NR) GenBank protein database and 6 matched with hypothetical proteins (Supplemental Table S4 online).

Among the most strongly down-regulated genes was, as expected, *NaLecRK1* ($\log_2(\text{FC})=-3.1$) and, interestingly, threonine deaminase (*TD*; $\log_2(\text{FC})=-2.3$; Supplemental Table S4). Additional genes down-regulated in *ir-lecRK1* plants and potentially associated to defense responses were *N. attenuata* homologues of a putative protease inhibitor-I from *Nicotiana sylvestris* and of a protein from *N. tabacum* able to induce hypersensitive-response-like lesions. In the group of up-regulated genes with a predicted function in defense responses, a putative PR-10 type pathogenesis-related protein was 6-fold up-regulated in *ir-lecRK1* compared to WT (Supplemental Table S4 online).

Among the remaining genes that changed expression were *N. attenuata* homologues of genes involved in the regulation of gene expression (e.g., *HTA11* (*Histone H2A variant 1*), *PAF1* (*Parafibromin 1*)), metabolic enzymes (e.g., *CK1* (*Choline kinase 1*), *CSLD2* (*cellulose synthase-like D2*), thiamine biosynthesis protein ThiC) and signal transduction components (e.g., phytochrome F and *NAP1-2* (*NUCLEOSOME ASSEMBLY PROTEIN 1;2*; Supplemental Table S4 online and see Discussion).

Threonine deaminase down-regulation in *ir-lecRK1* plants affects the levels of ingested Thr by *M. sexta* larvae.

Based on the microarray results and knowing that threonine deaminase (TD) plays important roles in defense responses against lepidopteran larvae in both tomato (Chen *et al.*, 2005) and *N. attenuata* (Kang *et al.*, 2006b), we reasoned that the reduced levels of expression of this gene in *ir-lecRK1* plants could contribute to the reduced defense response observed in these plants during *M. sexta* herbivory. To validate the microarray results, the transcript levels of *NaTD* were first quantified by qPCR in leaves of *ir-lecRK1* and WT plants at different times after *M. sexta* OS elicitation. *NaTD* mRNA levels were reduced by 75% and 50% at 30 and 60 min after the treatment, respectively, in *ir-lecRK1* compared to WT plants (Figure 7A).

Chapter 4

Second, the levels of Thr were quantified in the midgut content and tissue of *M. sexta* larvae fed for 11 continuous days on either WT, ir-lecRK1 or *N. attenuata* plants with reduced levels of NaTD (as-tdm2; (Kang et al., 2006b). The larvae were dissected to isolate the midgut and to separate the midgut tissue from its contents. In parallel, the leaves of the plants were also harvested after 11 days of larval feeding and used to quantify Thr amounts. The Thr levels in the midgut tissue of *M. sexta* larvae fed on ir-lecRK1-378 and as-tdm2 plants were 34% and 50% higher, respectively, than the Thr levels in the midgut tissue of larvae fed on WT plants (Figure 7B). The Thr levels in the midgut content of the larvae fed on ir-lecRK1-378 and as-tdm2 plants were 70% and 60% higher, respectively, than the Thr levels found in the midgut content of larvae fed on WT plants (Figure 7C). Due to the high water content in the midgut content, in this case Thr levels were expressed as mol% of the levels of all amino acids (Figure 7C). In leaves, the levels of Thr and JA-Ile were similar between WT, as-tdm2 and ir-lecRK1-378 plants (Figures 7D and 7E) whereas the levels of SA were 100% higher in ir-lecRK1-378 plants compared to WT and as-tdm2 plants (Figure 7F).

Figure 7. Reduced threonine deaminase (NaTD) expression in ir-lecRK1 plants affect threonine accumulation in the midgut of *M. sexta* larvae.

(A) NaTD mRNA levels quantified by qPCR in leaves of rosette stage WT and ir-lecRK1-378 plants at different times after *M. sexta* OS elicitation. The values are expressed as the fold-change (FC) increase relative to time 0 (value set arbitrary at 1). Transcript levels were calculated relative to the expression level of NaEF1A mRNA using the ΔCT method; see Materials and Methods). *: $P < 0.05$, Student's t-test (WT vs. ir-lecRK1-378 at same time point, bars denote $\pm SE$, $n=3$).

(B) Mean ($\pm SE$) of threonine (Thr) levels in midgut tissue of *M. sexta* larvae fed on either WT, ir-lecRK1-378 or as-tdm2 for 11 days. The larvae were chilled on ice and dissected to separate the midgut tissue from the midgut content (one sample contains the midguts from 3 larvae) and a total of 5 samples were analyzed ($n=5$). *: $P < 0.05$, Student's t-test (WT vs. genotype).

(C) Thr levels expressed in mol% as a molar percentage of all amino acids in the midgut content of *M. sexta* larvae fed on the plant genotypes described in (B). One sample contains the midgut content of 3 larvae and a total of 5 samples per plant genotype were analyzed ($n=5$). *: $P < 0.05$, Student's t-test (WT vs. genotype).

(D) Mean ($\pm SE$) of Thr levels in leaf tissue from WT, ir-lecRK1-378 and as-tdm2 plants 11 days after *M. sexta* feeding (one sample consists of 3 leaves pooled from different plants, $n=5$).

(E) Mean ($\pm SE$) of JA-Ile levels in leaf tissue from WT, ir-lecRK1-378 and as-tdm2 plants 11 days after *M. sexta* feeding (one sample consists of 3 leaves pooled from different plants, $n=5$).

(F) Mean ($\pm SE$) of SA levels in leaf tissue from WT, ir-lecRK1-378 and as-tdm2 plants 11 days after *M. sexta* feeding (one sample consists of 3 leaves pooled from different plants, $n=5$).

Figure 7. Reduced threonine deaminase (NaTD) expression in *ir-lecRK1* plants affect threonine accumulation in the midgut of *M. sexta* larvae. (see figure caption in page 66)

Chapter 4

The increased *M. sexta*-elicited SA burst in ir-lecRK1 plants suppresses the induction of defense responses in *N. attenuata* leaves

The results presented in the previous section showed that, during continuous *M. sexta* larval feeding, similar levels of JA-Ile accumulate in WT and ir-lecRK1 plants but increased SA levels in the latter. Based on these results and the increased accumulation of SA in ir-lecRK1 plants upon *M. sexta* OS elicitation (Figure 3E), we reasoned that the increased performance of *M. sexta* larvae on ir-lecRK1 plants could be the result of an SA-mediated suppression of induced defense responses. To test this hypothesis, transgenic *N. attenuata* plants ectopically expressing the *Pseudomonas putida nahG* gene under the control of the CaMV35S promoter (ov-nahG; Supplemental Figure S10 online) were generated and crossed with ir-lecRK1-378 plants to generate ir-lecRK1xov-nahG plants. As a control, ir-lecRK1-378 plants were also crossed with WT plants to generate ir-lecRK1xWT plants. It is important to note at this point that the basal levels of SA in ov-nahG and WT plants were similar however after a treatment that strongly induces SA levels (e.g., leaf infiltration with pathogenic bacteria), the accumulation of SA was strongly suppressed in ov-nahG plants (Supplemental Figure S10 online), indicating that the ectopic expression of *nahG* efficiently prevented the accumulation of induced levels of SA.

The levels of SA were first quantified in WT, ir-lecRK1-378, ov-nahG, ir-lecRK1xov-nahG and ir-lecRK1xWT plants at 3 h after OS elicitation (Figure 8A). SA levels were 2-fold higher in ir-lecRK1 and in ir-lecRK1xWT plants compared to WT and similar to WT levels in ov-nahG and ir-lecRK1xov-nahG plants (Figure 8A). The levels of SA were also quantified in leaves of these plants at 11 days after larval feeding and the results were similar to those observed after OS elicitation (Supplemental Figure S11A online). Thus, introgression of the *nahG* gene in ir-lecRK1 plants suppressed the OS- and *M. sexta*-elicited SA burst in these plants. The levels of JA and JA-Ile were also quantified in leaves at 11 days after *M. sexta* larval feeding and the accumulation of these two molecules was similar between the genotypes (Supplemental Figures S11B and S11C online).

Chapter 4

Freshly hatched *M. sexta* neonates were placed on the 5 genotypes mentioned above and the larval masses were determined at 4, 7, and 11 days after the start of the experiment. Strikingly, larvae feeding on ir-lecRK1xov-nahG gained similar masses to those larvae growing on WT and ov-nahG plants (Figure 8B). In contrast, larvae performed similarly on ir-lecRK1-378 and ir-lecRK1xWT plants (*i.e.* the larvae gained on average 80% the mass of larvae feeding on WT plants (Figure 8B)).

The induced levels of total HGL-DTGs in ir-lecRK1xov-nahG plants were similar to those in ov-nahG and WT plants and 2-fold higher compared to the levels in ir-lecRK1-378 and ir-lecRK1xWT plants (Figure 8C). The levels of induced TPI activity in lecRK1xov-nahG and ov-nahG plants were statistically similar to WT plants and higher than in ir-lecRK1 and ir-lecRK1xWT plants (Figure 8D). Induced nicotine levels were increased by 15% in ir-lecRK1xov-nahG compared to ir-lecRK1 plants but remained 14% lower than in WT (Figure 8E). Finally, NaTD transcript levels were increased 3-fold in ir-lecRK1xov-nahG compared to ir-lecRK1 plants however the levels remained 2-fold lower than in WT plants (Figure 8F). In summary, the suppression of SA accumulation in ir-lecRK1 plants restored the induced levels of HGL-DTGs and TPI activity to WT levels while induced nicotine levels and NaTD expression were partially restored.

Chapter 4

Figure 8. Suppression of SA accumulation in *ir-lecRK1* plants recovers the defense response against *M. sexta* herbivory.

(A) Mean (\pm SE) of SA levels quantified in leaves of rosette stage WT, *ir-lecRK1-378*, *ov-nahG*, *ir-lecRK1-378xov-nahG* and *ir-lecRK1-378xWT* plants. Leaves were elicited with *M. sexta* OS and harvested 3 h after the treatment (coincident with the peak of SA accumulation, Figure 3E). Different letters indicate significant differences (univariate ANOVA; $F_{4,13} = 18.17$, $P < 0.001$, followed by a Tukey HSD *post-hoc* test, $P < 0.05$, $n=3$).

(B) Mean (\pm SE) mass gain of *M. sexta* larvae fed on the 5 plant genotypes described in (A) for 4, 7 and 11 days. Different letters denote statistical significance (repeated-measurement ANOVA, $F_{8,4} = 35.06$, $P < 0.01$, $n=30$).

(C) Mean (\pm SE) of total HGL-DTGs quantified in leaves of the genotypes described in (A) at 3 days after elicitation with *M. sexta* OS (univariate ANOVA, $F_{4,14} = 58.78$, $P < 0.001$, followed by a Tukey HSD *post-hoc* test, $P < 0.05$, $n=3$).

(D) Mean (\pm SE) of nicotine quantified in leaves of the genotypes described in (A) at 3 days after elicitation with *M. sexta* OS (univariate ANOVA, $F_{4,22} = 10.45$, $P < 0.001$, followed by a Tukey HSD *post-hoc* test, $P < 0.05$, $n=4-5$).

(E) Mean (\pm SE) of TPI activity quantified in leaves of the genotypes described in (A) at 3 days after elicitation with *M. sexta* OS (univariate ANOVA, $F_{4,23} = 10.62$, $P < 0.001$, followed by a Tukey HSD *post-hoc* test, $P < 0.05$, $n=5$).

(F) *NaTD* mRNA levels quantified by qPCR in leaves of the genotypes described in (A) at different times after elicitation with *M. sexta* OS. The values are expressed as described in the caption for Figure 7A (univariate ANOVA, $F_{4,13} = 27.13$, $P < 0.001$, followed by a Tukey HSD *post-hoc* test, $P < 0.05$, $n=3$).

DISCUSSION

NaLecRK1 encodes for a G-type lectin receptor kinase

Lectin receptor kinases (LecRKs) belong to the family of receptor kinases with approximately 86 members in Arabidopsis (Bouwmeester and Govers, 2009). Based on the type of lectin domain, 3 types of LecRKs can be distinguished: C, L and G (Bouwmeester and Govers, 2009). C-type LecRKs are calcium-dependent lectin receptor-like kinases, L-type LecRKs contain a lectin domain with sequence similarity to legume lectins and G-type LecRKs (previously categorized as B-type) contain a lectin domain with sequence similarity to mannose-specific lectins of bulbous plant species (Bouwmeester and Govers, 2009).

NaLecRK1 belongs to the G-type LecRK family and the best studied members of this subfamily are the S-locus receptor kinases that function in self-incompatibility mechanisms during pollination (Takayama and Isogai, 2005). Recently, some G-type LecRKs have also been associated to defense responses against pathogenic microorganisms. For example, the rice Pi-d2 LecRK protein participates in the resistance mechanisms against *Magnaporthe grisea* (Chen *et al.*, 2006) and NgRLK1 from *N. glutinosa* participates in the resistance mechanisms against *Phytophthora capsici* (Kim *et al.*, 2010). In the group of L-type LecRKs, NbLRK1 from *N. benthamiana* interacts with the *P. infestans* elicitor INF1 and triggers INF1-induced cell death (Kanzaki *et al.*, 2008) and the Arabidopsis LecRK-I.9 has been identified as a putative mediator of cell wall-plasma membrane adhesion during infection with *Phytophthora* species (Bouwmeester *et al.*, 2011). LecRK-I.9 binds to a *P. infestans* effector protein through an RGD (Arg-Gly-Asp) motif which is also present as a cell-attachment motif in extracellular matrix (ECM) proteins that mediate cell adhesion to the cell walls (Bouwmeester *et al.*, 2011). In this study we show that lecRKs also participate in mechanisms regulating the induction of defense responses against folivorous insects.

Although the actual ligand of NaLecRK1 is at present unknown and even though it is speculative at this point, one possibility is that NaLecRK1 recognizes the disruption of cell walls (either by the perception of cell wall fragments or changes in the cell wall structure)

Chapter 4

occurring during *M. sexta* herbivory and thereby triggers changes that affect SA accumulation and the induction of defense responses. In Arabidopsis, the induction of defense responses mediated by JA and ET has been linked to changes in the cell wall structure as exemplified by the *cev1* (*constitutive expression of VSP1*) mutant which carries a genetic lesion in a cellulose synthase gene (Ellis *et al.*, 2002). Moreover, folivorous insects disrupt cell walls and it has been previously shown that cell wall fragments can activate defense responses in plants (Ryan *et al.*, 1993). This hypothesis requires further investigation.

The induction of NaLecRK1 expression is tightly controlled by OS/FACs and jasmonates

Elicitation of leaves from WT *N. attenuata* plants with OS from the generalist *Spodoptera exigua* induces the accumulation of SA to levels higher than those induced by OS from the specialist *M. sexta* whereas the latter induces the accumulation of higher levels of JA and ET (Diezel *et al.*, 2009). The same study showed that the lower levels of *M. sexta* OS-elicited SA are brought about by a suppression of SA accumulation mediated by enhanced ET levels however pathways independent of ET also operate (Diezel *et al.*, 2009). As a final outcome, the induction of defense responses is attenuated after elicitation of leaves with *S. exigua* OS compared to *M. sexta* OS (Diezel *et al.*, 2009).

In *ir-lecRK1* plants, elicitation of leaves by *M. sexta* OS and larval folivory induced the accumulation of SA to levels 2-fold higher than those in WT plants, suggesting that NaLecRK1 is one signal transduction component operating during *M. sexta* herbivory to suppress SA accumulation. Interestingly, the levels of ET produced by *ir-lecRK1* plants were similar to those produced by WT plants, indicating that the NaLecRK1-mediated signaling pathway works in a pathway independent of the ET-mediated suppression of SA accumulation (Diezel *et al.*, 2009).

Analysis of NaLecRK1 mRNA expression in plants deficient in JA biosynthesis or perception suggested that jasmonates inhibit the induction of this gene (Figure 1C). Moreover, plants with reduced expression of NaSIPK and NaWIPK showed that these two

Chapter 4

regulatory components effect positively the expression of the *NaLecRK1* gene, consistent with their central role in the activation of defense responses against *M. sexta* herbivory (Wu *et al.*, 2007; Figure 9). These results revealed that the induction of *NaLecRK1* expression is under tight control; it is induced by OS/FAC elicitation but the levels of induction are checked by jasmonates (in a COI1-dependent manner) which are also produced after OS/FAC elicitation. Thus, in this case, jasmonate levels would tune *NaLecRK1* expression and thereby the accumulation of SA levels during insect herbivory (Figure 9).

The induced accumulation of central defense metabolites is affected by reducing expression of *NaLecRK1* in *N. attenuata* plants

When *N. attenuata* plants are reduced either in the accumulation of HGL-DTGs or nicotine or in the expression of TPI or *NaTD*, *M. sexta* larvae feeding on these plants can gain from 50 to 300% more mass than larvae feeding on WT plants (Jassbi *et al.*, 2008b)). Consistent with these previous studies, an increased performance of *M. sexta* larvae on *ir-lecRK1* plants was accompanied with reductions in the induced accumulation of these defense metabolites or proteins (Figures 5, 6 and 7).

In agreement with the role of TD in the deamination of Thr in the insect gut (Chen *et al.*, 2005), the levels of Thr in the midgut tissue and content of *M. sexta* larvae fed on *ir-lecRK1* were 34% and 70 % higher, respectively, than the level of Thr in the midgut tissue and content of larvae fed on WT plants (Figure 7B and C). Also in agreement with the role of *NaTD* in the supplying of Ile for JA-Ile biosynthesis in leaves after *M. sexta* OS elicitation (Kang *et al.*, 2006), the accumulation of JA-Ile was reduced on average by 30% at 1 h after this treatment (Figure 3D). However, after 11 days of continuous *M. sexta* larval feeding, the levels of JA-Ile were similar between WT and *ir-lecRK1* plants (Figures 7E), indicating that the reduced levels of *NaTD* expression in the latter did not affect the accumulation of JA-Ile after several days of larval feeding. This effect could be brought about, for example, by changes in the metabolism of JA-Ile in *ir-lecRK1* plants. It has been shown that not only the biosynthesis but also the metabolism of JA-Ile is tightly regulated in plants, as exemplified by the miss-regulated accumulation of JA-Ile in plants with reduced expression

Chapter 4

of COI1 (Paschold *et al.*, 2008; VanDoorn *et al.*, 2011). Importantly, together with the 2-fold increased levels of SA observed after 11 days of *M. sexta* larvae continuous feeding (Figure 7F), the results suggested that the reduced induction of nicotine, HGL-DTGs, TPI and NaTD levels was not the results of reduced JA-Ile accumulation whereas of a suppressive effect of SA.

NaLecRK1 suppresses SA accumulation during *M. sexta* herbivory allowing the unfettered induction of defense responses

Although the levels of OS- and *M. sexta*-elicited SA were only moderately increased (2-fold) in *ir-lecRK1* plants (Figures 3E, 7F, 8A and Supplemental Figure S11A online), the reduction of SA levels in *ir-lecRK1xov-nahG* plants (Figure 8A) was sufficient to recover the defense response as determined by *M. sexta* larval performance (Figure 8B). Moreover total HGL-DTG levels and TPI activity were fully recovered in *ir-lecRK1xov-nahG* plants (Figures 8C and D), suggesting that the accumulation of these compounds was fully inhibited by SA in *ir-lecRK1* plants. In contrast, nicotine levels were only partially recovered in *lecRK1xov-nahG* plants compared to WT plants (Figure 8E). This partial recovery was probably due to the fact that nicotine levels were significantly reduced by 15% in *ov-nahG* plants compared to WT, indicating that the ectopic expression of *nahG* has a slight negative effect on nicotine accumulation (Figure 8E). However, *M. sexta* larvae performed similarly on WT and *ov-nahG* plants (Figure 8A), indicating that defense responses were not impaired in the latter. Consistently, the levels of HGL-DTGs, TPI activity, and NaTD expression were not significantly different between WT and *ov-nahG* plants (Figure 8C, D and F).

Similar to induced nicotine accumulation, NaTD expression was also partially recovered in *ir-lecRK1xov-nahG* plants compared WT and since NaTD expression levels were statistically similar between WT and *ov-nahG* plants, this partial recovery was probably the result of a partial involvement of the OS-elicited SA burst in the suppression of NaTD expression in *ir-lecRK1* plants (Figure 8F).

Chapter 4

In summary, these results showed that the suppression of the OS/*M. sexta*-elicited SA burst in *ir-lecRK1* plants decreased the performance of *M. sexta* larvae and that this suppression was sufficient to fully restore the induced accumulation of HGL-DTGs and TPI activity and to partially restore the induced accumulation of nicotine and NaTD expression in *ir-lecRK1* plants to levels in WT plants.

Additional changes in the metabolome and transcriptome affected by reduced expression of *NaLecRK1*

Even though the work was primarily focused on the effect of *NaLecRK1* on known defense responses in *N. attenuata*, the accumulation of 148 ions were affected in *ir-lecRK1* plants compared to WT (Supplemental Table S2 online). The identity of most of the corresponding metabolites could not be unambiguously determined and remains the focus of future work. Some of these metabolites may also be critical for the interaction between *M. sexta* and *N. attenuata* and their accumulation may also be affected by increased OS-elicited SA levels (in a manner similar to the defense metabolites analyzed in detail in this study). Consistent with the number of ions detected as differentially regulated in *ir-lecRK1* versus WT plants, a previous study has identified 173 metabolites as differentially regulated in *N. attenuata* WT plants at 1 h and 5 days after *M. sexta* elicitation (Gaquerel *et al.*, 2010). Thus, from these numbers it can be preliminary concluded that *NaLecRK1* has a prominent effect on the accumulation of metabolites induced by *M. sexta* OS elicitation in leaves of *N. attenuata* plants. This effect is however specific to some degree since the induction of defense metabolites derived from the phenyl-propanoid pathway were not affected in *ir-lecRK1* plants (Supplemental Figure S9 online).

Gene expression analysis of leaf tissue from *ir-lecRK1* and WT plants at 1 h after *M. sexta* OS elicitation showed that the reduced expression of *NaLecRK1* affects the accumulation of 77 transcripts (using the conditions described in the Results section) and, based on gene ontology annotation (Supplemental Table S4 online), the functions of these genes were distributed among diverse cellular processes (e.g., defense, metabolism, transcriptional regulation, transport and oxidative-reduction processes). What is the role of

Chapter 4

these genes in the response of *N. attenuata* plants to *M. sexta* herbivory is at present unknown and the focus of future work.

The unraveling of the complexity of the changes occurring in the metabolome and transcriptome of *ir-lecRK1* plants during *M. sexta* herbivory will provide further insights into additional mechanisms controlled by *NaLecRK1* and affecting the response of *N. attenuata* to *M. sexta* herbivory.

Figure 9. Proposed model for the role of *NaLecRK1* in the *N. attenuata* defense response against *M. sexta*.

During herbivory by *M. sexta* larvae, the FACs present in the larval OS induced the expression of the *NaLecRK1* gene. This induction depends on the activity of SIPK and WIPK which in parallel activate the biosynthesis of JA (Kallenbach *et al.*, 2010). JA is conjugated to Ile to form JA-Ile and TD supplies Ile for this biosynthetic process (Kang *et al.*, 2006). JA-Ile induces the accumulation of defense metabolites or proteins (including nicotine, TPIs, HGL-DTGs and TD) via COI1-dependent mechanisms (Paschhold *et al.*, 2007; Heiling *et al.*, 2010) and inhibits the expression of *NaLecRK1*. *NaLecRK1* suppresses the SA burst induced by *M. sexta* herbivory which in turn allows for an unfettered induction of the defense metabolites nicotine, TPIs, HGL-DTGs and TD. LOX3: lipoxygenase 3; 13-HPOT: 13S-hydroperoxy-octadecatrienoic acid; SIPK, salicylate-induced protein kinase; WIPK, wound-induced protein kinase, threonine deaminase (TD).

Chapter 4

MATERIALS AND METHODS

Plant growth and treatments

Seeds of the 31st generation of an inbred line of *N. attenuata* plants were used as the wild-type (WT) genotype in all experiments. Seeds from WT and genetically transformed plants were germinated as previously described (Krügel *et al.*, 2002). Plants were grown in the glasshouse under high-pressure sodium lamps (200-300 $\mu\text{mol s}^{-1} \text{m}^{-2}$ light) with a day/night cycle of 16 h(26-28°C)/8 h(22-24°C) and 45 to 55% humidity. Crosses between *N. attenuata* lines were performed by removing anthers from flowers of homozygous *ir-lecRK1-378* plants before pollen maturation and by brushing the stigma with pollen from homozygous plants ectopically expressing the *nahG* gene (*ov-nahG*) or WT. For wounding and elicitation treatments, leaves were wounded by rolling a fabric-pattern wheel three times on each side of the midvein and the wounds were supplemented either with 20 μL of water (wounding treatment), 20 μL of 18:3-Glu (0.03 nmol/ μL ; FAC elicitation) or 20 μL of *M. sexta*, *S. littoralis* or *S. gregaria* OS diluted 1:5 (v/v) in water (OS elicitation). Tissue expression profile of *NaLecRK1* was evaluated by collecting different plant tissues from WT *N. attenuata* plants; rosette leaves and roots were collected from 30 day-old (rosette stage; Figure 2C) plants whereas stems, systemic leaves, sepals, pistils, corolla, inflorescence and stamens were collected from 50 day-old (early flowering) plants.

Insect rearing, feeding experiments and OS collection

Larvae of the tobacco hornworm (*Manduca sexta* L., Lepidoptera, Sphingidae) were obtained from in-house colonies. One freshly hatched larva of *M. sexta* was placed on the leaf of early rosette stage (Figure 2C) *N. attenuata* plants ($n=30$). Larval mass was determined using a microbalance after 4, 7 and 11 days of the start of the experiment. OS from *M. sexta* and *S. littoralis* reared on *N. attenuata* WT plants were collected as described by Roda *et al* (2004) and OS from *S. gregaria* were collected as described by Schäfer *et al* (2011). For the estimation of the leaf area consumed after 11 days of *M.*

Chapter 4

sexta larval feeding, 20 leaves in which larvae has fed were excised (one leaf per plant per genotype was used) and scanned (CanoScanLide20 scanner, Cannon). The area consumed was calculated by subtracting the total leaf area (estimated by reconstruction of the leaf contour) to the remaining leaf area.

Virus induced gene silencing

Virus-induced gene silencing (VIGS) based on the tobacco rattle virus (TRV; Ratcliff *et al.*, 2001) was used to transiently silenced *NaLecRK1* as previously described (Saedler and Baldwin, 2004). An 86 bp fragment corresponding to the 3'-UTR of *NaLecRK1* (see accession number below) was amplified by PCR with the primers LecRK1-33 and LecRK1-30 (Supplemental Table S5 online). The PCR product was digested with *Bam*H1 and *Sal*I and inserted into plasmid pTV00 in antisense orientation to generate the VIGS-lecRK1 vector. Plants transformed with the empty vector (EV) were used as control. Efficiency of gene silencing was evaluated by real-time qPCR (see below) using the primers 5358 Fw and 5358 Rv (Supplemental Table S5 online) 1 h after wounding and 18:3-Glu elicitation.

Generation of stable silenced lines

The same 86 pb fragment used for generating the VIGS-lecRK1 vector was subcloned into the pSOL8 transformation vector (Bubner *et al.*, 2006) as an inverted-repeat construct. This construct was used to transform *N. attenuata* WT plants using *Agrobacterium*-mediated transformation and plant regeneration as previously described (Krügel *et al.*, 2002). T₁ transformed plants were analyzed for T-DNA insertion number by Southern blot hybridization (see below). Segregation analysis for hygromycin resistance in T₂ seedlings was performed on agar plates supplemented with hygromycin (0.025 mg ml⁻¹). Two lines, A-08-378-5-4-1 (ir-lecRK1-378) and A-08-380-6-3-8 (ir-lecRK1-380) had a single T-DNA insertion in the genome and they were used for all experiments. For Southern blot analysis, genomic DNA from WT and ir-lecRK1 plants was isolated by the cetyltrimethylammonium bromide (CTAB) method. DNA samples (10 µg) were digested

Chapter 4

with *EcoRV* (New England Biolabs, Frankfurt, Germany) overnight at 37°C according to commercial instructions and separated on a 1% (w/v) agarose gel using standard conditions. DNA was blotted onto Gene Screen Plus Hybridisation Transfer membranes (Perkin Elmer Life and Analytical Sciences, Boston, MA) using the capillary transfer method. A gene-specific probe for the hygromycin resistance gene *hptII* was generated by PCR using the primers HYG1-18 and HYG3-20 (Supplemental Table S5 online). The probe was labeled with [α -³²P]dCTP (Perkin Elmer) using the Rediprime II kit (Amersham Pharmacia, Freiburg, Germany) according to commercial instruction. Efficiency of gene silencing was evaluated by qPCR (see below) after 1 h of wounding and 18:3-Glu treatment using the primers 5358 Fw and 5358 Rv (Supplemental Table S5 online).

For the generation of *N. attenuata* plants ectopically expressing the bacterial salicylate hydroxylase gene (*nahG*) from *Pseudomonas putida*, a 690 bp fragment corresponding to this gene was amplified with primers NahG1-33 and NahG1-34 (Supplemental Table S5 online) using *P. putida* genomic DNA as template and subcloned into the pSOL1 vector (Bubner *et al.*, 2006) to generate pSOL1-nahg1 and this vector was used to transform *N. attenuata* WT plants using *Agrobacterium*-mediated transformation as previously described (Krügel *et al.*, 2002). Segregation analysis for hygromycin resistance in T₂ seedlings was performed on agar plates supplemented with hygromycin (0.025 mg mL⁻¹) and homozygous T₂ transformed plants were analyzed for expression of the *nahG* gene by RT-PCR using the primers NahG1-Fw and NahG1-Rv (Supplemental Table S5 online). For Southern blot analysis, genomic DNA was isolated as described above. DNA samples (10 µg) were digested with *EcoRV* and *DraI* (New England Biolabs) overnight at 37°C according to commercial instructions and separated on a 1% (w/v) agarose gel using standard conditions. DNA was blotted onto nylon membranes as described above. Membranes were hybridized with a nahG-specific radio-labeled probe that was generated by PCR using the primer pairs NahG1 Fw and NahG1 Rv (Supplemental Table S5 online) and [α -³²P]dCTP (Perkin Elmer) using the Rediprime II kit (Amersham Pharmacia) according to commercial instruction. *Pseudomonas syringe* DC3000 (Pst DC3000) grown at O.D. = 0.001 or water (control) was syringe-infiltrated into leaves of WT and ov-nahG plants and infiltrated leaf tissue was harvested 2 days after the treatment for analysis of SA levels (see below).

Chapter 4

Rapid amplification of cDNA ends and sequence analysis

For cloning of the full length *NaLecRK1* cDNA sequence, 5 µg of total RNA were isolated from leaves of *N. attenuata* plants. The 3'RACE and 5'RACE Systems for Rapid Amplification of cDNA Ends (Invitrogen, Karlsruhe, Germany) were used following the manufacturer's instructions and the primers listed in Supplemental Table S5 online. The PCR products were cloned into the pGEM-T easy vector (Promega, Madison, WI) and sequenced using universal primers. Sequence alignments were performed using BLAST (<http://blast.ncbi.nlm.nih.gov>) and ExPASy (<http://expasy.org>). Structural domain prediction was performed using SMART (<http://smart.embl-heidelberg.de>; Letunic *et al.*, 2009) and Pfam (<http://pfam.sanger.ac.uk>) databases. Prediction of transmembrane domains was performed using TMHMM (<http://www.cbs.dtu.dk/services/TMHMM>) and SOSUI (<http://bp.nuap.nagoya-u.ac.jp/sosui>) web servers. Prediction of signal peptides was performed using SignalP 3.0 (<http://www.cbs.dtu.dk/services/SignalP>).

Quantitative real-time PCR

For all treatments, *N. attenuata* rosette leaves were harvested and immediately frozen in liquid nitrogen. Total RNA was extracted using the TRIzol[®] reagent (Invitrogen) and 5 µg of total RNA were reverse transcribed using oligo(dT)₁₈ and SuperScript reverse transcriptase II (Invitrogen). Quantitative real-time PCR (qPCR) was performed with a Mx3005P Multiplex qPCR system (Stratagene, La Jolla, CA) and the qPCR Core kit for SYBR[®] Green I (Eurogentec, Liege, Belgium). Relative quantification of mRNA levels was performed by the comparative ΔC_t method using the eukaryotic elongation factor 1A (*NaEF1A*) mRNA as an internal standard (Gilardoni *et al.*, 2010). The sequences of the primers used for qPCR are listed in Supplemental Table S5 online. All the reactions were performed with three biological replicates using the following qPCR conditions: initial denaturation step of 95°C for 30 s, followed by 40 cycles each of 95°C for 30 s and 60°C for 1 min, with a final extension step of 95°C for 30 s and 60°C for 1 min.

Chapter 4

Phytohormone extraction and quantification

For analysis of JA, JA-Ile and SA, 0.1 g of frozen leaf tissue was homogenized to a fine powder with a Geno/Grinder 2000 (BTC and OPS Diagnostics, Bridgewater, USA) in the presence of liquid nitrogen. One mL of ethylacetate spiked with 200 ng [$^2\text{H}_2$]JA and [$^2\text{H}_4$]SA and 40 ng JA-[$^{13}\text{C}_6$]Ile was added to the samples and after vortexing the samples were centrifuged for 15 min at 12,000xg (4°C). The upper organic phase was transferred into a fresh tube and the leaf material was re-extracted with 0.5 mL ethylacetate without internal standards. The organic phases were pooled and evaporated to dryness under reduced pressure. The dry residue was reconstituted in 0.4 mL of 70/30 (v/v) methanol/water for analysis with an LC-ESI-MS/MS instrument (Varian 1200 Triple-Quadrupole-LC-MS system; Varian, Palo Alto, CA). Ten μL of the sample were injected in a ProntoSIL[®] column (C18-ace-EPS, 50 x 2 mm, 5 μm , 120 Å, Bischoff, Leonberg, Germany) connected to a pre-column (C18, 4 x 2mm, Phenomenex, Torrance, CA). As mobile phases 0.05% formic acid in water (solvent A) and methanol (solvent B) were used in a gradient mode with the following conditions: time/concentration (min/%) for B: 0.0/15; 2.5/15; 4.5/98; 10.5/98; 12.0/15; 15.0/15; time/flow (min/mL min⁻¹): 0.0/0.4; 1.5/0.2; 1.5/0.2; 10.5/0.4; 15.0/0.4. Compounds were detected in the ESI negative mode and multiple reaction monitoring (MRM) according to the parameters previously published (Bonaventure *et al.*, 2011b).

For the analysis of ET, the youngest fully expanded leaf of rosette stage *N.attenuata* plants was either wounded or OS elicited and it was immediately excised, weighed and transferred into a 250-mL glass vessel. Five leaves per treatment and genotype were used ($n=5$). After a 5 h incubation period (glass vessels were kept in the glasshouse under the same conditions as the plants), the headspace of the vessels was flushed into a laser photo-acoustic spectrometer (PAS; INVIVO, Adelzhausen, Germany) for determination of ET levels as previously described (Körner *et al.*, 2009). Ethylene emissions are expressed as $\text{nL h}^{-1}\text{g}^{-1}$ fresh weight. Untreated leaves were used to determine basal ET levels.

Chapter 4

Metabolic profiling of leaves by UPLC-ToF-MS

One hundred milligrams of leaf tissue were ground with a Geno/Grinder 2000 (BTC and OPS Diagnostics) in the presence of liquid nitrogen and thoroughly extracted with 1 mL of extraction buffer (40% (v/v) methanol/water; 50 mM acetate buffer (pH 4.8)). Homogenized samples were centrifuged at 12,000xg for 20 min at 4°C, the supernatant was transferred into a fresh 1.5 mL microcentrifuge tube and the samples were centrifuged again using the same conditions. 100 µL of the supernatant were transferred into HPLC vials.

Four µL of the leaf extract were injected into a C18 Acclaim column (2.2 µm particle size, 150 mm x 2.1 mm inner diameter; Dionex Corp., Sunnyvale, USA) and separated using a RSLC system (Dionex). Solvent A was de-ionized water containing 0.1 % (v/v) acetonitrile (Baker, HPLC grade) and 0.05 % (v/v) formic acid. Solvent B was acetonitrile and 0.05 % (v/v) formic acid. The gradient condition was applied as follows: 0 – 0.5 min 10 % B, 0.5 – 6.5 min linear gradient 80 % B, 6.5 – 10 min 80 % B, and re-equilibration at 10 % B for 3 min. The flow rate was 300 µL min⁻¹. Eluted compounds were detected with a MicroToF mass spectrometer (Bruker Daltonik, Bremen, Germany) equipped with an electrospray ionization source in positive ion mode. Instrument settings were as follows: capillary voltage, 4500 V; capillary exit, 130 V; dry gas temperature, 200 °C; dry gas flow, 8 L min⁻¹. Mass calibration was performed using sodium formate clusters (10 mM solution of NaOH in 50/50% (v/v) isopropanol/water containing 0.2% formic acid). Data sets were evaluated from 125 to 550 sec in the mass range *m/z* 90 to 1400. The raw data files were converted to netCDF format using the export function of the Data Analysis version 4.0 software (Bruker Daltonics, Bremen, Germany) and processed using the XCMS package (Tautenhahn *et al.*, 2008) and the R-package CAMERA (<http://www.bioconductor.org/biocLite.R>) as previously described (Gaquerel *et al.*, 2010). Peak detection was performed using the centWave method (Tautenhahn *et al.*, 2008) and the parameter settings ppm=20, snthresh=10, peakwidth=5 to 20 s. Retention time (RT) correction was achieved using the parameter settings minfrac=1, bw=60 s, mzwid=0.1D, span=1, and missing=extra=0 (Gaquerel *et al.*, 2010).

Chapter 4

The Metaboanalyst software ((Xia et al., 2009) was used to perform multivariate analysis (PCA and PLSDA). The data was filtered using the coefficient of variation (CV) and it was normalized using Pareto scaling ((Xia et al., 2009) Gaquerel *et al.*, 2010). PLSDA ((Eriksson L, 2006; Xie et al., 2008) was validated using a permutation test as previously described (Westerhuis *et al.*, 2008). An important output of the PLSDA analysis is that it estimates and ranks the influence of individual features (ions) on the model by assigning to each variable a VIP (variable importance in the projection) value, VIP values bigger than or equal to 1.0 are considered statistical significant for group discrimination (Xie *et al.*, 2008; Mazzara *et al.*, 2011). For elemental molecular formula calculation, the SmartFormula algorithm (Data-Analysis 4.0 software, Bruker Daltonik) was used following maximum elemental composition $C_aH_bN_cO_dNa_eK_f$ and the restrictions $1 \leq b/a \leq 3$; $e=0$ or 1 ; $f=0$ or 1 ; a , b , c , and d not limited. Rings plus double bonds values from -0.5 to 40, the nitrogen rule, and ions of even electron configuration were also considered (Gaquerel *et al.*, 2010). The public metabolite databases used for analysis were Prime (<http://prime.psc.riken.jp/>), Metlin (<http://metlin.scripps.edu/>), MetDAT2 (<http://www.sdwa.nus.edu.sg/METDAT2/>), KEEG (<http://www.genome.jp/kegg/>), PubChem (<http://pubchem.ncbi.nlm.nih.gov/>) and Knapsack (<http://kanaya.naist.jp/KNAPSAck/>).

Analysis of TPI activity

Leaf tissue from 40-day-old *ir-lecRK1-378*, *ir-lecRK-380* and WT plants was harvested 2 and 3 days after wounding and *M. sexta* OS elicitation. Unelicited tissue was used as control for basal TPI activity. 100 mg of leaf tissue were ground using a Geno/Grinder 2000 (BTC and OPS Diagnostics) in 2 mL microcentrifuge tubes and extracted with 0.3 mL of ice-cold extraction buffer (0.1 M Tris-Cl (pH 7.6), 5% (w/w) polyvinylpolypyrrolidone (Sigma), 2 mg/mL phenylthiourea (Sigma), 5 mg/mL diethyldithiocarbamate (Sigma), 0.05 M Na_2EDTA). The samples were thoroughly vortexed and centrifuged at 4°C for 20 min at 12,000xg. The supernatant was transferred into a fresh tube and kept on ice for protein quantification and TPI analysis. Protein concentration was determined with the Protein Assay kit (Bio-Rad, München, Germany) using bovine

Chapter 4

serum albumina (BSA; Sigma) as a standard. TPI activity was analyzed by a radial diffusion assay as previously described (Van Dam *et al.*, 2001).

Analysis of HGL-DTGs, nicotine and phenyl-propanoid derivatives.

For quantification of total HGL-DTGs and nicotine levels, leaf samples were harvested after the treatments and times indicated in the figure captions and homogenized to a fine powder with a Geno/Grinder 2000 (BTC and OPS Diagnostics). Samples were extracted with 40% (v/v) methanol/water containing 0.5% (v/v) acetic acid and analyzed by HPLC as previously described (Keinänen *et al.*, 2001; Jassbi *et al.*, 2008). An external calibration curve was generated with a dilution series of nicotine and glycyrrhizinic acid and samples were normalized by gram fresh weight (gFW⁻¹). Individual HGL-DTG species were quantified by reverse-phase LC-MS/MS as previously described (Heiling *et al.*, 2010). Derivatives of the phenyl-propanoid pathway were analyzed as previously described (Kaur *et al.*, 2010).

Amino acid determination in *M. sexta* midgut and leaf tissue

M. sexta larvae reared on *N. attenuata* plants for 11 days were placed on ice and their midguts were dissected with forceps under a stereomicroscope. The midgut tissue and content were separated and immediately transferred into screw cap 10 mL glass tubes placed on ice. Midgut tissue and content were homogenized separately in the presence of 1 mL 1/1 (v/v) chloroform/methanol containing 0.01% (v/v) formic acid. After centrifugation for 15 min at 700xg (4°C), the supernatant was transferred into a fresh 10 mL glass tube and the aqueous phase/tissue was re-extracted with 1 mL chloroform. After centrifugation for 15 min at 700xg (4°C), the supernatants were pooled and transferred into 4 mL HPLC vials. Midgut and midgut content were diluted 1/40 (v/v) in water before analysis. Leaves were extracted using the same protocol but diluted 1/1 (v/v) in water before analysis. Chromatography was performed on an Agilent 1200 HPLC system (Agilent Technologies, Boeblingen, Germany) using a Zorbax Eclipse XDB-C18 column (50 x 4.6 mm, 1.8 µm,

Chapter 4

Agilent Technologies). Formic acid (0.05%) in water and acetonitrile were employed as mobile phases A and B, respectively. The elution profile was: 0-1 min, 100% A; 1-3 min, 0-100% B in A; 3-4 min 100% B and 4.1-7 min 100% A. The mobile phase flow rate was 0.8 mL min⁻¹. The column temperature was maintained at 25°C. An API 3200 tandem mass spectrometer (Applied Biosystems, Darmstadt, Germany) equipped with a Turbospray ion source was operated in positive ionization mode. The instrument parameters were optimized by infusion experiments with pure threonine standard (Sigma). The ionspray voltage was maintained at 5500 eV. The turbo gas temperature was set at 700 °C. Nebulizing gas was set at 70 psi, curtain gas at 35 psi, heating gas at 70 psi and collision gas at 2 psi. Multiple reaction monitoring (MRM) was used to monitor analyte parent ion → product ion as described by Jander *et al* (2004). External calibration curves for amino acids were created by linear regression in the range from 0.2 to 5 µM.

Starch quantification

Leaf samples were harvested at different times after *M. sexta* OS elicitation and homogenized to a fine powder with a Geno/Grinder 2000. Samples were extracted with 1 mL 80% (v/v) ethanol/water and centrifuged at 12,000xg for 15 min at 4°C. The pellet was washed with 1 mL 80% (v/v) ethanol/water and centrifuged at 12,000xg for 15 min. 500 µL of water were added to the pellet and the samples were vortexed for 5 min. 650 µL of perchloric acid (Carl-Roth, Karlsruhe, Germany) was added and the samples were completely homogenized by pipetting several times up and down with a micropipette. The homogenates were incubated on ice for 20 min and then centrifuged at 12,000xg for 15 min at 4°C. The starch-containing supernatant was transferred to a new 1.5 mL microcentrifuge tube and 10 µL were diluted with 90 µL of water. 400 µL of anthrone reagent (100 mg anthrone (Sigma-Aldrich) in 100 mL 95% (v/v) H₂SO₄/water (Carl-Roth)) were added and the reactions were kept for 8 min in a boiling water bath (Viles and Silverman, 1949). After samples cooled down, absorbance was measured at 630 nm with the Ultrospec[®] 3000 (Pharmacia Biotech, Cambridge, England) spectrophotometer. Standard curves were generated with D-glucose (Sigma-Aldrich) from 0.05 to 1 mg/mL.

Chapter 4

Microarray analysis

Total RNA was extracted based on the method of Kistner and Matamoros (2005) and its quality checked by spectrophotometry (NanoDrop, Wilmington, DE). Genomic DNA was removed by DNase treatment following commercial instructions (Turbo DNase; Ambion, Europe), RNA was cleaned up with RNeasy MinElute columns (Qiagen, Hilden, Germany) and the RNA quality was checked with the RNA 6000 Nano kit (Agilent, Santa Clara, CA) using an Agilent 2100 Bioanalyzer. Total RNA was used to generate labeled cRNA with the Quick Amp labeling kit (Agilent) following commercial specifications and the yield of cRNA was determined spectrophotometrically (NanoDrop). Labeled cRNA was hybridized using the Gene Expression Hybridization kit (Agilent) following commercial instructions onto a 44K custom designed 60mer *N. attenuata* Agilent microarrays (Kallenbach *et al.*, 2011) containing 43,533 sequences (see Accession numbers). Microarrays were hybridized overnight at 65°C and slides were washed with the Gene Expression Wash Buffer kit (Agilent) as outlined in the One-Color Microarray-Based Gene Expression Analysis manual (Agilent). Three biological replicates were used per treatment with a total of six arrays (see Accession numbers). Arrays were scanned with an Agilent G2565BA scanner and image data was acquired with the Agilent Scan Control software (version A.7.0.1 for the B scanner). Data was extracted using the Agilent Feature Extraction software (version 9.5) and analyzed with the SAM (Significance Analysis of Microarrays) software (Tusher *et al.*, 2001). The q-values for each gene corresponded to a computed false discovery rate (FDR) of 4%. Significant changes in gene expression were considered when the \log_2 (fold change; treatment versus control) were greater than 1.3 or smaller than -1.3 and q-values lower than 0.05 (according to the FDR value calculated by SAM).

Chapter 4

Statistical analysis

Statistics were calculated using the SPSS software version 17.0.

Accession numbers

Na*LecRK1* (JF919621), Agilent Chip platform (GPL13527; NCBI GEO database), microarray data (GSE29905; NCBI GEO database).

ACKNOWLEDGMENTS

PG is a fellow of the Deutscher Akademischer Austausch Dienst (DAAD). We thank E. Gaquerel for his help with the analysis of the metabolic profiling data and M. Reichelt for his assistance with amino acid analysis. This work was funded by the Deutsche Forschungsgemeinschaft (DFG; Project BO3260/3-1) and the Max Planck Society.

AUTHOR CONTRIBUTIONS

P.G. carried out the experiments, analyzed the data and wrote the manuscript. C.H. characterized and provided the ov-nahg plants. I.T.B. participated in the design and coordination of the study and wrote the manuscript. G.B. conceived of the study, participated in its design and coordination and wrote the manuscript.

Supplemental figures

Supplemental Figure S1. Protein alignment of NaLecRK1 with lecRKs from different plants species.

The amino acid sequence of NaLecRK1 was aligned using ClustalW with homologous sequences of lecRKs from different plant species: S-receptor kinase from *Arabidopsis thaliana* (GenBank Accession CAA16960.1); NbLRK1 from *Nicotiana benthamiana* (GenBank Accession BAG68210.1); Pi-d2 from *Oryza sativa* (GenBank Accession ACR15163.1); and NgRLK1 from *Nicotiana glutinosa* (GenBank Accession ACI26722.1). The blue line marks the position of the conserved lectin domain and the green line marks the position of the conserved Ser/Thr kinase domain.

Chapter 4

Supplemental Figure S2. Analysis of plants reduced in NaLecRK1 expression by VIGS.

N. attenuata plants with reduced levels of *NaLecRK1* expression were generated by virus induced gene silencing (VIGS; NaLecRK1-VIGS). EV-VIGS were plants transformed with the empty vector (EV).

(A) Leaves from EV-VIGS and NaLecRK1-VIGS plants were wounded and supplemented with water or 18:3-Glu and leaf tissue was harvested 1 h after the treatments. *NaLecRK1* mRNA levels were quantified by qPCR. The values are expressed as the fold-change (FC) increase relative to time 0 (value set arbitrary at 1). Transcript levels were calculated relative to the expression level of NaEF1A mRNA using the ΔCT method; see Materials and Methods). *: $P < 0.05$, Student's t-test, (EV-VIGS vs. NaLecRK1-VIGS same treatment, bars denote $\pm\text{SE}$, $n=5$).

(B) Mean ($\pm\text{SE}$) of *M. sexta* larval mass after 4, 7 and 11 of feeding on EV-VIGS or NaLecRK1-VIGS plants. Statistical analysis was performed by repeated-measurement ANOVA ($F_{1,56} = 34.242$, $P < 0.01$; $n=32$), asterisks indicate significant differences between larvae feeding on EV-VIGS and those feeding on NaLecRK1-VIGS plants.

Chapter 4

Supplemental Figure S3. Starch and protein levels in *ir-lecRK1* plants after OS elicitation.

Leaves from WT and *ir-lecRK1* plants were elicited with *M. sexta* OS at 6 pm of the day before tissue harvesting started (6 am). Leaf tissue was harvested at the times indicated in the x-axis during a period of 3 days.

(A) Mean (\pm SE) of starch levels in WT and *ir-lecRK1* plants ($n=5$).

(B) Mean (\pm SE) of total protein levels in WT and *ir-lecRK1* plants ($n=5$).

Supplemental Figure S4. Quantification of JA, JA-Ile and SA levels in *ir-lecRK1* plants after wounding.

Leaves from WT and *ir-lecRK1* plants were wounded and leaf tissue was harvested at different times after the treatment for phytohormone analysis by LC-MS/MS.

(A) Mean (\pm SE) of JA levels in WT and *ir-lecRK1* plants ($n=4$).

(B) Mean (\pm SE) of JA-Ile levels in WT and *ir-lecRK1* plants ($n=4$).

(C) Mean (\pm SE) of SA levels in WT and *ir-lecRK1* plants ($n=4$).

Supplemental Figure S5. Ethylene analysis in leaves of WT and ir-lecRK1 plants after wounding and OS elicitation.

Leaves of rosette stage WT and ir-lecRK1 (378 and 380) plants were either wounded or elicited with *M. sexta* OS and the levels of ethylene produced by excised leaves during a 5 h period were determined by photo-acoustic spectrometer (PAS). Bars denote $\pm \text{SE}$. ($n=5$). Untreated leaves were used to determine basal ET levels.

Chapter 4

Supplemental Figure S6. PCA and validation of PLSDA analysis of ions accumulating differentially in ir-lecRK1 plants.

Leaves from rosette stage *N. attenuata* WT and ir-lecRK1-378 plants were elicited with *M. sexta* OS and leaf tissue was harvested at 12 h and 3 and 6 days after the treatments. After extraction, polar metabolites were analyzed by UPLC-ToF-MS in the positive ion detection mode as described in Materials and Methods.

(A) Hierarchical clustering analysis of 148 ions differentially accumulating in ir-lecRK1 plants compared to WT plants (fold change data was log₂ transformed before analysis; correlation (uncentered) as similarity metrics).

(B) PCA analysis of the 148 ions differentially accumulating in ir-lecRK1 plants. Components 1 and 2 explained together 64.7% of the variance of the samples (the explained variances per component are shown in brackets). Ellipses delimit the 95% statistical confidence areas for each biological group in the score plots.

(C) Validation of the PLSDA analysis (see Figure 4B) by the permutation test described by Westerhuis *et al.* (2008). y-axis, Probability distribution (Frequency).

Supplemental Figure S7. Analysis of nicotine, HGL-DTGs and TPI activity in ir-lecRK1 plants after wounding.

Leaves of rosette stage WT, ir-lecRK1-378 and ir-lecRK1-380 plants were wounded and leaf tissue was harvested 3 days after the treatment for analysis of nicotine and HGL-DTG accumulation and TPI activity.

(A) Mean (\pm SE) of nicotine quantified by HPLC ($n=4$).

(B) Mean (\pm SE) of total HGL-DTGs quantified by HPLC ($n=4$).

(C) Mean (\pm SE) of TPI activity analyzed by a radial diffusion assay ($n=4$).

Supplemental Figure S8. Kinetic of NaGGPPs and NaTPI transcript accumulation in ir-lecRK1 plants.

(A) Leaves from rosette stage WT and ir-lecRK1-378 plants were elicited with *M. sexta* OS. NaGGPPs mRNA levels were quantified by qPCR. The values are expressed as the fold-change (FC) increase relative to time 0 (value set arbitrary at 1). The NaGGPPs mRNA levels were calculated relative to the expression level of NaEF1A mRNA using the ΔCT method; see Materials and Methods). *: $P < 0.05$, Student's t-test, (WT vs. ir-lecRK1-378 plants at same time point, bars denote $\pm\text{SE}$, $n=3$).

(B) Leaves from rosette stage WT and ir-lecRK1-378 plants were elicited with *M. sexta* OS. NaTPI mRNA levels were quantified by qPCR and expressed as described in (A). *: $P < 0.05$, Student's t-test (WT vs. ir-lecRK1-378 plants at same time point, bars denote $\pm\text{SE}$, $n=3$).

Chapter 4

Supplemental Figure S9. Analysis of derivatives of the phenyl-propanoid pathway.

Leaves of rosette stage WT, ir-lecRK1-378 and ir-lecRK1-380 plants were either wounded or elicited with *M. sexta* OS (W+OS). Leaf tissue was harvested 3 days after the treatments and the samples were analyzed by HPLC. Untreated plants served as controls for basal levels of the metabolites analyzed.

(A) Mean (\pm SE) of caffeoylputrescine ($n=4$).

(B) Mean (\pm SE) of dicaffeoylspermidine ($n=4$).

(C) Mean (\pm SE) of chlorogenic acid ($n=4$).

(D) Mean (\pm SE) of rutin ($n=4$).

Chapter 4

Supplemental Figure S10. Analysis of *N. attenuata* plants ectopically expressing the *nahG* gene (ov-nahg).

(A) Analysis of *nahG* transcript levels in *N. attenuata* WT and T₂ homozygous ov-nahg plants by RT-PCR using primers NahG-1 and NahG-2 (supplemental Table S5 online). The PCR product of 690 bp corresponds to the *nahG* transcript.

(B) Analysis of T-DNA insertion number. 10 µg of genomic DNA from WT and ov-nahg plants was digested with *EcoRV* and *DraI*, the digested DNA was resolved by agarose gel electrophoresis and blotted onto a nylon membrane. The membrane was hybridized with a NahG-specific ³²P-radiolabeled probe generated by PCR using the primer pairs NahG-1 and NahG-2. The ov-nahg line harbored a single T-DNA insertion (arrows).

(C) To evaluate SA metabolism by the *nahG* gene product in ov-nahg plants, the levels of SA in WT and ov-nahg plants were quantified after inoculation of leaves with *Pseudomonas syringae* DC3000 (*Pst* DC3000). *Pst* DC3000 bacteria growing in the early exponential phase (O.D. = 0.001) were resuspended in water and syringe-infiltrated into leaves and SA levels were analyzed in the same leaves at 2 days after infiltration. The control treatment consisted of inoculation with water (mock). Asterisks indicate significant differences between wt and ov-nahg plants (Student's t-test; *: $P < 0.001$ (WT vs ov-nahg); $n = 10$). The morphology of ov-nahg plants was indistinguishable from that of WT plants at all developmental stages (not shown).

Chapter 4

Supplemental Figure S11. Levels of SA, JA and JA-Ile in 5 different genotypes after *M. sexta* herbivory.

Freshly hatched *M. sexta* neonates were allowed to feed on WT *N. attenuata* plants and ir-lecRK1-378, ov-nahg, ir-lecRK1-378 x ov-nahg and ir-lecRK1-378 x WT plants for 11 days. Leaf tissue was harvested from these plants at this time point and used to quantify SA, JA and JA-Ile levels by LC-MS/MS.

(A) Mean (\pm SE) of SA levels (univariate ANOVA, $F_{4,13} = 10,57$ $P < 0.002$, followed by a Tukey HSD post-hoc test, $P < 0.05$, $n=3$).

(B) Mean (\pm SE) of JA levels ($n=3$).

(C) Mean (\pm SE) of JA-Ile levels ($n=3$).

Key words: herbivory, hydroperoxide lyase (HPL), lipoxygenase (LOX), oxylipin, tobacco (*Nicotiana attenuata*), traumatic acid, traumatin.

- In response to diverse stresses, the hydroperoxide lyase (HPL) pathway produces C₆ aldehydes and 12-oxo-(9Z)-dodecenoic acid ((9Z)-traumatin). Since the original characterization of (10E)-traumatin and traumatic acid, little has been added to our knowledge of the metabolism and fluxes associated with the conversion of (9Z)-traumatin into diverse products in response to wounding and herbivory.
- A liquid chromatography–mass spectrometry/mass spectrometry (LC-MS/MS) method was developed to quantify C₁₂ derivatives of the HPL pathway and to determine their metabolism after wounding and simulated herbivory in *Nicotiana attenuata* leaves.
- Ninety-eight per cent of the (9Z)-traumatin produced was converted to 9-hydroxy-(10E)-traumatin (9-OH-traumatin); two-thirds by product recycling through lipoxygenase-2 (NaLOX2) activity and one-third by nonenzymatic oxidation. Thirty-eight per cent of the *de novo* produced 9-OH-traumatin was conjugated to glutathione, consistent with this oxylipin being a reactive electrophile species. 12-OH-(9Z)-dodecenoic and dodecenedioic acids also showed rapid increases after wounding and simulated herbivory and a role for C₁₂ derivatives as signals in these processes was consistent with their ability to elicit substantial changes in gene expression.
- These results underscore the importance of metabolite reflux through LOX2, an insight which creates new opportunities for a functional understanding of C₁₂ derivatives of the HPL pathway in the regulation of stress responses.

Abbreviations: (10E)-traumatin, 12-oxo-(10E)-dodecenoic acid; (9Z)-traumatin, 12-oxo-(9Z)-dodecenoic acid; 13S-HPODE, 13S-hydroperoxy-(9Z,11E)-octadecadienoic acid; 13S-HPOTE, 13S-hydroperoxy-(9Z,11E)-octadecatrienoic acid; 4-OH-traumatic acid, 4-hydroxy-(2E)-dodecenedioic acid; 9,12-hydroxy-(10E)-dodecenoic acid, 9,12-OH-(10E)-dodecenoic acid; 9,12-OH-(10E)-dodecanoic acid, 9,12-hydroxy-(10E)-dodecanoic acid; 9-OH-traumatin, 9-hydroxy-12-oxo-(10E)-dodecenoic acid; traumatic acid, (2E)-dodecenedioic acid.

Introduction

In plants, the production of oxylipins from polyunsaturated fatty acids (PUFAs) is immediately induced in response to diverse stresses including wounding, and insect and pathogen attacks (Turner *et al.*, 2002; Farmer *et al.*, 2003; Mueller, 2004; Taki *et al.*, 2005; Matsui, 2006; Browse, 2009; Mosblech *et al.*, 2009). Oxylipins are diverse in structure and they play essential roles as signaling molecules during the plant's responses to these environmental stresses.

For example, jasmonic acid is essential for the induction of defense responses against pathogens and insect herbivores (Farmer *et al.*, 2003; Kessler *et al.*, 2004; Browse, 2005), C₆ aldehydes are important signals acting during pathogenesis and plant–insect communication (Croft *et al.*, 1993; Matsui, 2006; Baldwin, 2010), C₁₂ diacids and ω-oxo-acids were originally described as wound-associated hormones (Bonner & English, 1937; Zimmerman & Coudron, 1979), divinyl ethers inhibit mycelial growth and spore germination of some oomycete species (Prost *et al.*,

2005) and phytoprostanes play diverse roles in biotic stress responses (Loeffler *et al.*, 2005).

13-lipoxygenases (13-LOXs) initiate the enzymatic biosynthesis of oxylipins by di-oxygenating PUFAs such as linoleic (18:2^{Δ9,12}; 18:2) and α -linolenic (18:3^{Δ9,12,15}; 18:3) acids to generate 13S-hydroperoxy dienoic (13S-HPODE) and trienoic (13S-HPOTE) acids, respectively. Hydroperoxide lyase (HPL) cleaves 13S-HPODE and -HPOTE to generate the green leaf volatiles (GLVs) hexanal and (3Z)-hexenal, respectively, and 12-oxo-(9Z)-dodecenoic acid ((9Z)-traumatol; compound 1a in Fig. 1) (Vick & Zimmerman, 1976). In *Nicotiana attenuata* leaves, the supply of 13S-HPODE and 13S-HPOTE for the biosynthesis of hexanal and (3Z)-hexenal requires the activity of the lipoxygenase-2 gene (*NaLOX2*); plants with reduced expression of this gene have a greatly reduced production of GLVs (Allmann *et al.*, 2010). *Nicotiana attenuata* plants with reduced expression of *NaHPL* have similarly reduced production of GLVs (Halitschke *et al.*, 2004 and this study).

Hexanal, (3Z)-hexenal and (9Z)-traumatol undergo rapid modifications by diverse enzymatic and nonenzymatic reactions, generating multiple potential chemical signals. These modifications involve, among others, the isomerization of double bonds (Z to E), the oxidation of the aldehyde groups to carboxyl groups, their reduction to alcohols and their esterification (Grechkin, 2002). These modifications change the physicochemical properties of the molecules, and in some cases their importance in biological processes has been demonstrated (Zimmerman & Coudron, 1979; Ivanova *et al.*, 2001; Allmann & Baldwin, 2010). In the case of (9Z)-traumatol, the Z double bond isomerizes to E to form 12-oxo-(10E)-dodecenoic acid ((10E)-traumatol; compound 1b in Fig. 1), and the aldehyde group can auto-oxidize to form (3Z)- or (2E)-dodecenedioic acid ((3Z)- or (2E)-traumatic acid; compounds 2a and 2b in Fig. 1) (Zimmerman & Coudron, 1979) or be reduced to form (9Z)- or (10E)-12-hydroxy-dodecenoic acid (12-OH-dodecenoic acid; compounds 3a and 3b in Fig. 1) (Grechkin, 2002). (9Z)-traumatol can be oxidized to 9-hydroxy-12-oxo-(10E)-dodecenoic acid (9-OH-traumatol; compound 4 in Fig. 1) either enzymatically by a LOX-mediated mechanism (Gardner, 1998) or nonenzymatically (Noordermeer *et al.*, 2000). A recent study showed that 9-OH-traumatol can be subsequently converted into 4-hydroxy-(2E)-dodecenedioic acid (4-OH-traumatic acid; compound 5 in Fig. 1), 9,12-hydroxy-(10E)-dodecenoic acid (9,12-OH-(10E)-dodecenoic acid; compound 6 in Fig. 1) and 9,12-hydroxy-(10E)-dodecenoic acid (9,12-OH-(10E)-dodecenoic acid; compound 7 in Fig. 1) in pea (*Pisum sativum*) seedlings (Mukhtarova *et al.*, 2011). 9-OH-traumatol belongs to a class of oxylipins defined as oxylipin-reactive electrophile species (RES) based on their chemical reactivity, which in turn results from an α - β unsaturated carbonyl group (Gardner, 1998;

Farmer & Davoine, 2007; Mueller & Berger, 2009) (Fig. 1). Moreover, the presence of the hydroxyl group at C-4 of the α - β unsaturated carbonyl group increases the reactivity of C-3 to nucleophiles such as thiols and amines (Esterbauer *et al.*, 1976; Uchida, 2003).

In the case of C₁₂ derivatives of the HPL pathway, early experiments have shown that (10E)-traumatol and (2E)-traumatic acid have growth-stimulating and wound-healing activities in plants (Bonner & English, 1937, 1938; English & Bonner, 1937; Zimmerman & Coudron, 1979) and, more recently, 12-OH-(9Z)-dodecenoic acid has been shown to act as a potent stimulator of the mitotic cycle (Ivanova *et al.*, 2001). In recent years, research has been focused primarily on the biochemical and functional characterization of GLVs during herbivore and pathogen attacks, and less attention has been paid to the metabolism and signal capacities of the C₁₂ derivatives of the HPL pathway. As a result, the metabolic fluxes and fates of these molecules under these stress conditions are largely unknown in plants. These shortcomings hamper the development of new hypotheses concerning the potential roles of these molecules as signals. Hence, in this study we present a detailed analysis of the fluxes and metabolism of C₁₂ derivatives of the HPL pathway in *N. attenuata* plants induced by wounding and simulated herbivory. Part of this analysis is based on a new liquid chromatography–mass spectrometry/mass spectrometry (LC-MS/MS) method developed for the quantification of these metabolites. We reveal new aspects of the biogenesis of the C₁₂ derivatives of the HPL pathway and open new perspectives for possible roles of these metabolites in the regulation of stress responses.

Materials and Methods

Plant growth and treatments

Seeds of *Nicotiana attenuata* Torr. ex S. Watson wild-type (WT), *ir-lox2* (line 52-2) (Allmann *et al.*, 2010), *ir-lox2/ir-lox3* (Kallenbach *et al.*, 2010) and *ir-hpl* (line 428-8; Supporting Information Methods S1) plants were germinated on agar plates containing Gamborg's B5 medium as previously described (Krügel *et al.*, 2002). Plates were maintained in a growth chamber (Snijders Scientific, Tilburg, the Netherlands) at 26°C : 16 h (155 $\mu\text{mol s}^{-1} \text{m}^{-2}$ light), 24°C : 8 h dark for 10 d. Ten-day-old seedlings were transferred to TEKU pots (Pöppelmann GmbH & Co. KG, Lohne, Germany) with Klasmann plug soil (Klasmann-Deilmann GmbH, Geesten, Germany). After 10 d, seedlings were transferred to soil in 1-l pots and grown in the glasshouse under high-pressure sodium lamps (200–300 $\mu\text{mol s}^{-1} \text{m}^{-2}$) with a day : night ratio of 16 h (26–28°C) : 8 h (22–24°C) and 45–55% humidity.

Leaf wounding was performed by rolling a fabric pattern wheel three times on each side of the midvein of the leaves

Fig. 1 Schematic representation of the hydroperoxide lyase (HPL) pathway in plants and the generation of derivatives of 12-oxo-(9Z)-dodecenoic acid ((9Z)-traumatin). In leaves, 18:2 and 18:3 fatty acids are released from membranes and dioxygenated by 13-lipoxygenases (13-LOXs) to generate 13S-hydroperoxides (13-HPODE and 13-HPOTE, respectively). These molecules are substrates of HPL and are cleaved to produce C₆ aldehydes and (9Z)-traumatin (compound 1a). This molecule can undergo several enzymatic and nonenzymatic modifications to be converted into the products (10E)-traumatin (compound 1b), (3Z)-traumatic acid (compound 2a), (2E)-traumatic acid (compound 2b), 12-OH-(9Z)-dodecenoic acid (compound 3a), 12-OH-(10E)-dodecenoic acid (compound 3b) and 9-OH-traumatin (compound 4). The latter compound can be converted into 4-OH-traumatic acid (compound 6), 9,12-OH-(10E)-dodecenoic acid (compound 5) and 9,12-OH-(10E)-dodecanoic acid (compound 4) according to Mukhtarova *et al.* (2011). The formation of 9-OH-traumatin by LOX-mediated activity has been proposed by Gardner (1998), whereas its nonenzymatic formation has been proposed by Noordermeer *et al.* (2000).

of 40-d-old rosette-stage plants, and the wounds were immediately supplemented with water. For fatty acid-amino acid conjugate (FAC) elicitation, the wounds were immediately supplemented with 20 µl of synthetic *N*-linolenoyl-glutamic acid (18:3-Glu; 0.03 nmol µl⁻¹). Leaf tissue was collected at different times after the treat-

ments and was frozen immediately in liquid nitrogen (N) for subsequent analysis. For C₁₂ treatments, leaves from *ir-lox2/ir-lox3* plants were wounded as described above and a 1 : 1 mixture of (9Z)-traumatin:9-OH-traumatin (1 µg each per leaf dissolved in 0.02% aqueous Tween-20) or solvent (control treatment) was immediately applied to the wounds.

Purchased chemicals and synthesis of C₁₂ derivatives of the HPL pathway

(9*Z*)-traumatin and (10*E*)-traumatin were purchased from Larodan (Malmö, Sweden); (2*E*)-traumatic acid was purchased from Sigma (Taufkirchen, Germany). 12-OH-(9*Z*)-dodecenoic acid and 12-OH-(10*E*)-dodecenoic acid were synthesized by reduction of 25 µg of (9*Z*)-traumatin or (10*E*)-traumatin, respectively, with excess NaBH₄ in 1 ml of ethanol for 4 h at 0°C. After acidification with HCl to pH 4, the products were purified by reverse solid-phase extraction (SPE) on a C18 column (Vac C18 3cc; Waters, Eschborn, Germany) by washing with water and eluting with methanol. 9-OH-traumatin was generated *in vitro* by two different methods: nonenzymatic oxidation (Noordermeer *et al.*, 2000); and processing of *N. attenuata* leaf extracts using the protocol described in the section 'In vitro assays with leaf extracts'. 9-OH-traumatin was fractionated by reverse-phase HPLC on a Gemini-NX® column (C18; 3 µm, 150 × 2 mm; Phenomenex, Aschaffenburg, Germany) using methanol and water as running solvents in a gradient mode in a Dionex UPLC system (Dionex, Germering, Germany) equipped with a fraction collector (WPS3000-FC; Dionex). The structures of the synthetic 12-OH-dodecenoic acids and 9-OH-traumatin were confirmed by gas chromatography-mass spectrometry (GC-MS) analysis: the carboxyl group of 12-OH-dodecenoic acids was transmethylylated with diazomethane and the terminal hydroxyl group was silylated (trimethylsilyloxy ether (OTMSi)) by N-methy-N-(trimethylsilyl) trifluoroacetamide (MSTFA) (Machery-Nagel, Düren, Germany); the aldehyde group in 9-OH-traumatin was reduced with excess NaBH₄, the carboxyl group transmethylylated with diazomethane and the hydroxyl groups finally silylated (OTMSi) with MSTFA. GC-MS analyses were performed on a Varian CP-4000 GC coupled to a Varian Saturn 4000 ion trap MS in electron ionization (EI; 70 eV) mode (Varian, Palo Alto, CA, USA). One microliter of the sample was injected using a 1 to 10 split ratio on a DB-5 column (30 m × 0.25 mm i.d.; 0.25-µm film thickness; Agilent, Boeblingen, Germany) with helium at a constant flow of 1 ml min⁻¹ as the carrier gas. The injector was at 260°C. The oven temperature program was: 140°C for 2 min, 180°C at 6.0°C min⁻¹, 20°C min⁻¹ ramp to 240°C and hold for 1 min. Electron impact (EI) spectra were recorded in scan mode from 40 to 400 *m/z*.

The glutathione (GSH) adduct of 9-OH-traumatin was synthesized by mixing 10 µg of HPLC-purified 9-OH-traumatin with 13 µg of GSH in 1 ml of buffer (10 mM MOPS and 0.02% (v/v) Tween-20; pH 7.0) for 4 h at room temperature. The solution was reduced to *c.* 50 µl in an Eppendorf SpeedVac® (Eppendorf, Wesseling-Berzdorf, Germany) connected to a high-vacuum membrane pump (Varian SH100; Varian). Then 200 µl of methanol was added to the sample and the 9-OH-traumatin-GSH conju-

gate was purified by reverse-phase HPLC using a Dionex UPLC system as described for the purification of 9-OH-traumatin.

Analysis of synthetic standards, and detection and isomeric separation of C₁₂ derivatives of the HPL pathway in leaves

Optimization of the multiple reaction monitoring (MRM) parameters for LC-(electrospray ionization (ESI))-MS/MS analysis was carried out by direct injection of single analytes (1 ng µl⁻¹ in 70% (v/v) methanol/water) into the ESI-MS interface. Ionization was performed in the negative mode and the first quadrupole was set on their corresponding [M-H]⁻ masses (Table S1). The third mass analyzer was set in the scan mode, ranging from 50 to 350 *m/z*. The MS/MS fragmentation patterns of the analytes were obtained by collision-induced dissociation (CID) with argon gas in the second quadrupole with increasing collision energies. The parent > daughter (*m/z*) ion transitions that gave the highest intensities were used to optimize the separation and detection of the analytes, and the final parameters used are listed in Table S1.

For the chromatographic separation of the C₁₂ analytes and their *Z/E* isomers, 10 µl of standard solutions (1 ng µl⁻¹) was injected onto a Gemini-NX® column (C18; 3 µm, 50 × 2 mm; Phenomenex) connected to a pre-column (Gemini-NX; C18, 4 × 2 mm; Phenomenex). As mobile phases, 0.05% : 1% (v/v/v) formic acid : acetonitrile : water (solvent A) and methanol (solvent B) were used. The solvent gradient of the mobile phases was 5% of B for 2 min (pre-run), followed by a linear gradient to 45% of B to 6 min, 45% of solvent B to 22 min, a linear gradient to 98% of solvent B to 24 min, 98% of B to 27 min, a linear gradient to 5% of B to 28 min, and 5% of solvent B to 32 min. The total flow rates were 0.4 ml min⁻¹ for 0.5 min, 0.2 ml min⁻¹ from 0.5 to 26 min and 0.4 ml min⁻¹ to 32 min.

Extraction and quantification of C₁₂ derivatives of the HPL pathway in leaf extracts

For extraction, 0.3 g of frozen leaf material was homogenized in 2-ml tubes containing two steel beads (ASK, Korntal-Muenchingen, Germany) by shaking the tubes in a Genogrinder (SPEX Certi Prep, Metuchen, NJ, USA) for 30 s at 1300 strokes min⁻¹. One milliliter 2 : 1 (v/v) methanol : chloroform spiked with 200 ng of 10-hydroxy-(2*E*)-decenoic acid (internal standard (IS)) and containing 1% (w/v) butylhydroxytoluene (BHT) as a radical scavenger was added and the samples were vortexed for 10 min. After centrifugation for 10 min at 4°C (16 100 *g*), the organic phase was collected and the residual plant material was re-extracted with 0.5 ml of 2 : 1 (v/v) methanol : chloroform. The organic phases were combined and the solvent

was evaporated under reduced pressure avoiding complete dryness. The samples were reconstituted in 0.2 ml of 70% (v/v) methanol : water for analysis.

Analysis was performed on an LC-(ESI)-MS/MS system (Varian 1200 Triple-Quadrupole-LC-MS system; Varian). Ten microliters of the sample was injected onto a ProntoSIL[®] column (C18; 5 μ m, 50 \times 2 mm; Bischoff, Leonberg, Germany) connected to a precolumn (C18; 4 \times 2 mm; Phenomenex). As mobile phases, 0.05% : 1% (v/v/v) formic acid : acetonitrile : water (solvent A) and methanol (solvent B) were used in a gradient mode with the following conditions: time : concentration (min:%) for B: 0.0 : 5; 1.0 : 5; 8.0 : 98; 16.0 : 98; 17.0 : 5; 20.0 : 5; time : flow (min:ml min⁻¹): 0.0 : 0.4; 0.5 : 0.2; 15.5 : 0.2; 16.0 : 0.4; 20.0 : 0.4. Compounds were detected in the ESI negative mode and MRM (Table S2).

The response curves of the synthetic or purified C₁₂ analytes vs the IS (10-hydroxy-(2*E*)-decenoic acid) were determined and used to calculate the response factors (Fig. S4). For quantification of endogenous C₁₂ derivatives, the corresponding peak areas obtained in the LC chromatogram were integrated and divided by the peak area of the IS, and the values were corrected by the respective response factor. For determination of the linearity and the sensitivity of the method, the standards of all C₁₂ analytes were dissolved at different concentrations in a leaf matrix derived from unelicited *ir-lox2* plants. Linearity (as expressed by the correlation coefficient (*r*)) was calculated by the method of least squares and sensitivity was calculated by determining the limit of detection according to the calibration curve method (Fig. S2).

In vitro assays with leaf extracts

Per assay, one 50-mm² leaf disc was cut from rosette-stage *N. attenuata* plants with a cork borer and was gently and thoroughly crushed with a pestle in a 1.5-ml tube containing 0.2 ml of reaction buffer (10 mM MOPS and 15% (w/v) glycerol; pH 6.8). The sample was centrifuged at 4°C for 5 min at 2300 *g* to pull down tissue debris and the supernatant was kept on ice. The amount of protein in the extract was quantified using the Bio-Rad Protein Assay kit (Bio-Rad, München, Germany) and BSA as a standard. One microgram of either (9*Z*)-traumatoin or (10*E*)-traumatoin (dissolved in 10 μ l of 0.02% (v/v) Tween-20 : water) was added to 200 μ l of reaction buffer containing 100 μ g of total protein and the reaction was carried out at room temperature for different times. The reaction was stopped by the addition of 1 ml of 2 : 1 (v/v) chloroform : methanol containing 1 μ g of 10-hydroxy-(2*E*)-decenoic acid (IS) and 1% (w/v) BHT. After centrifugation (1 min at 16 100 *g*), the supernatant was collected and concentrated under a stream of N₂, avoiding complete dryness, and the samples were reconstituted in 1 ml of 70% (v/v) methanol : water for LC-MS/MS analysis as

described previously in the section 'Extraction and quantification of C₁₂ derivatives of the HPL pathway in leaf extracts'.

For LOX activity inhibition, a final concentration of 10 mM 3,4-dihydroxy-phenylethanol (DHPE; Sigma) was used in the reaction. Leaf extracts were heat-inactivated by incubation at 95°C for 5 min.

Analysis of surface-deposited C₁₂ derivatives of the HPL pathway

Unelicited and elicited leaves from rosette-stage *N. attenuata* plants were cut at the base of the petiole, weighed, and washed for 1 min in 8 ml of methanol. Then 500 ng of 10-hydroxy-(2*E*)-decenoic acid (IS) and 1% (w/v) BHT were added to the 8-ml wash. The remaining leaf material was extracted with 2 : 1 (v/v) methanol : chloroform containing 500 ng of 10-hydroxy-(2*E*)-decenoic acid (IS) and 1% (w/v) BHT. The solvent was evaporated under a stream of N₂, avoiding complete dryness, and both leaf wash and leaf samples were reconstituted in 0.5 ml of 70% (v/v) methanol : water for analysis by LC-MS/MS as described above in Extraction and quantification of C₁₂ derivatives of the HPL pathway in leaf extracts.

Microarray analysis

Total RNA was extracted based on the method of Kistner & Matamoros (2005) and its quality checked by spectrophotometry (NanoDrop, Wilmington, DE, USA). Genomic DNA was removed by DNase treatment following commercial instructions (Turbo DNase; Ambion), RNA was cleaned up using RNeasy MinElute columns (Qiagen, Hilden, Germany) and the RNA quality was checked with the RNA 6000 Nano kit (Agilent, Santa Clara, CA, USA) using an Agilent 2100 Bioanalyzer. Total RNA was used to generate labeled cRNA with the Quick Amp labeling kit (Agilent) and the yield was determined spectrophotometrically (NanoDrop). Labeled cRNA was hybridized using the Gene Expression Hybridization kit (Agilent) onto 44 K custom-designed 60-mer *N. attenuata* Agilent microarrays (sequences available upon request) containing 43 533 sequences. Microarrays were hybridized overnight at 65°C and slides were washed with the Gene Expression Wash Buffer kit (Agilent) as outlined in the One-Color Microarray-Based Gene Expression Analysis manual (Agilent). Three biological replicates were used per treatment with a total of six arrays. Arrays were scanned with an Agilent G2565BA scanner and image data were acquired with the Agilent SCAN CONTROL software (version A.7.0.1 for the B scanner). Data were extracted using the Agilent FEATURE EXTRACTION software (version 9.5) and analyzed with the SIGNIFICANCE ANALYSIS OF MICROARRAYS (SAM) software (Tusher *et al.*, 2001). The *q*-values for each gene corresponded to a computed false discovery rate (FDR) of

3.3%. Significant changes in gene expression were considered when the \log_2 (fold change; treatment vs control) was > 1 or < -1 and q -values < 0.035 (according to the FDR value calculated by SAM).

Statistical analysis

Statistics were calculated using the SPSS software version 17.0 (SPSS, Chicago, IL, USA).

Results

Development of a method for the analysis of C_{12} derivatives of the HPL pathway by LC-MS/MS

The standards (9Z)-traumatin, (10E)-traumatin, 12-hydroxy-(9Z)-dodecenoic acid, 12-hydroxy-(10E)-dodecenoic acid, 9-OH-traumatin, (2E)-traumatic acid, (3Z)-traumatic acid and 10-hydroxy-(2E)-decenoic acid (used as internal standard) were either purchased or synthesized (see the Materials and Methods section). These standards were first directly injected into the ESI-MS interface to determine their $[M-H]^-$ parent ion and their parent $>$ daughter (m/z) ion transitions by collision-induced dissociation (CID) using increasing voltage energies. The parent $>$ daughter (m/z) ion transitions giving the strongest intensity at fixed collision energies were selected (Tables S1,S2) for MRM during the chromatographic separation of the standards by LC. This separation was performed by reverse-phase LC and the method was first established for the separation of the *E* and *Z* stereoisomers of the standards (Fig. 2a).

Next, to determine the C_{12} derivatives of the HPL pathway that accumulated endogenously in leaves of *N. attenuata* plants, the method was applied to the analysis of leaf extracts from unelicited and wounded WT plants. (9Z)-traumatin, 9-OH-traumatin, (2E)-traumatic acid, (3Z)-traumatic acid, and 12-OH-(9Z)-dodecenoic acid were detected while (10E)-traumatin, 12-OH-(10E)-dodecenoic acid, 4-OH-traumatic acid, 9,12-OH-(10E)-dodecenoic acid and 9,12-OH-(10E)-dodecanoic acid were either absent or below the limit of detection (LoD; Table S2).

Based on these results, a shorter method that did not discriminate between the dodecenedioic acid isomers ((2E)- and (3Z)-traumatic acids) was developed for the quantification of C_{12} derivatives in a large number of samples. When this method was used, all C_{12} analytes eluted from the column within 13 min (Fig. 2b). The C_{12} analytes presented a linear response, with an r value of 0.99 and LoD values of $c. 1$ ng in the column (Fig. S2). The extraction method was validated by performing 10 biological replicates of *N. attenuata* unelicited and wounded leaves after 60 min of the treatment. For each replicate, 0.3 g of leaf tissue was extracted and analyzed by LC-MS/MS. The standard deviations of the calculated amounts were below 10% of the

average values for all detectable compounds. To determine the extraction recovery rate, the residual leaf material obtained after the extraction protocol was re-extracted and analyzed for the presence of C_{12} derivatives. The recovery rates were $> 98\%$ for all the molecules tested.

To corroborate the endogenous production of 9-OH-traumatin, leaf extracts from *N. attenuata* plants were supplied with (9Z)-traumatin and the products of the reaction were analyzed by GC-MS. Fig. 2(c) shows a chromatogram and the MS spectrum corresponding to 9-OH-traumatin. Formation of 11-OH-traumatin could not be detected in leaf extracts; however, it was detected when (9Z)-traumatin was subjected to auto-oxidation *in vitro* (Fig. S1), as previously described (Noordermeer *et al.*, 2000).

9-OH-traumatin is the most abundant C_{12} derivative accumulating after wounding and FAC elicitation in *N. attenuata* leaves

The endogenous accumulation of C_{12} molecules was first quantified in leaves of WT *N. attenuata* after wounding and simulated herbivory. For the latter treatment, wounds were supplemented with the fatty acid-amino acid conjugate (FAC) *N*-linoleyl-glutamic acid (18:3-Glu), a major elicitor of herbivore responses in this plant species (Halitschke *et al.*, 2001). The accumulation of C_{12} molecules was quantified in both treated (local) and distal (systemic) leaves.

In unelicited leaf tissue of early rosette-stage *N. attenuata* plants (40 d old), 9-OH traumatin accumulated to $c. 2$ nmol g^{-1} FW while (9Z)-traumatin, 12-OH-(9Z)-dodecenoic acid and dodecenedioic acids accumulated to < 0.1 nmol g^{-1} FW (Fig. 3). Fifteen minutes after wounding and FAC elicitation, 9-OH-traumatin concentrations increased on average to 8 and 10 nmol g^{-1} FW, respectively, and then decreased to reach on average 3 nmol g^{-1} FW after 8 h (Fig. 3). The concentrations of dodecenedioic acids and 12-OH-(9Z)-dodecenoic acid also increased several-fold rapidly after wounding and FAC elicitation; however, the absolute amounts remained below 0.25 nmol g^{-1} FW (Fig. 3). Analysis of earlier time-points (within 5 min) failed to show a rapid burst of (9Z)-traumatin after induction by wounding and FAC elicitation (data not shown), suggesting that this HPL product is rapidly utilized after production. In systemic leaves, no significant changes in the concentrations of these molecules were detected (data not shown).

NaLOX2 and NaHPL supply the substrates for the biosynthesis of (9Z)-traumatin

To validate the analysis of the C_{12} derivatives of the HPL pathway in *N. attenuata* leaves, *ir-lox2* plants with reduced expression of *NaLOX2* (Allmann *et al.*, 2010) and *ir-hpl* plants with reduced expression of *NaHPL* (Methods S1,

Fig. 2 Chromatographic profiles of C₁₂ derivatives of the hydroperoxide lyase (HPL) pathway. (a) Example of the chromatographic separation of Z/E isomers of C₁₂ standards. Compounds were separated by reverse phase on a Gemini-NX column, ionized by electrospray ionization (ESI) and detected in the multiple reaction monitoring (MRM) negative mode. (b) Example of the chromatographic separation of C₁₂ molecules obtained from leaf samples of wounded *Nicotiana attenuata* plants. Compounds were separated by reverse phase on a ProntoSIL column, ionized by ESI and detected in the MRM negative mode. Compounds: internal standard (IS), 10-OH-(2E)-decenoic acid; 1a, (9Z)-traumatin; 1b, (10E)-traumatin; 2a, (3Z)-traumatic acid; 2b, (2E)-traumatic acid; 3a, 12-OH-(9Z)-dodecenoic acid; 3b, 12-OH-(10E)-dodecenoic acid; 4, 9-OH-traumatin. (c) Leaf extracts from wild-type (WT) *N. attenuata* plants were supplied with 1 µg of (9Z)-traumatin for 1 h and subjected to reduction with NaBH₄, diazomethane derivatization and silylation (OTMSi) for gas chromatography–mass spectrometry (GC-MS) analysis. The mass spectrum shown in the insert corresponds to derivatized 9-OH-traumatin.

Figs S5, S6 and Table S4) were also analyzed. In unelicited leaves of *ir-lox2* plants, 9-OH-traumatin accumulated to < 0.2 nmol g⁻¹ FW (Fig. 4). Moreover, after wounding and FAC elicitation, the concentrations of this C₁₂ metabolite remained largely unchanged and the absolute concentrations were below 0.2 nmol g⁻¹ FW (Fig. 4). (9Z)-traumatin, 12-OH-(9Z)-dodecenoic acid and dodecenoic

acids were either not detected or accumulated to very low concentrations in leaves of *ir-lox2* plants (Fig. S3).

Analysis of *ir-hpl* plants showed that the concentrations of 9-OH-traumatin were reduced to c. 50% of WT concentrations in unelicited leaves and that they were increased twofold after wounding (Fig. 4a). After FAC elicitation, the concentrations of this metabolite increased but at lower

Fig. 3 Accumulation of C_{12} metabolites in leaves of wild-type (WT) *Nicotiana attenuata* plants after wounding and fatty acid-amino acid conjugate (FAC) elicitation. Leaves from WT plants were either wounded with a fabric pattern wheel (a) or subjected to wounding plus the addition of 18:3-Glu (b; FAC elicitation). Leaf samples were harvested at different times, extracted and the amounts of C_{12} derivatives of the hydroperoxide lyase (HPL) pathway (Fig. 1) were quantified by liquid chromatography-mass spectrometry/mass spectrometry (LC-MS/MS) (*, $P < 0.05$; **, $P < 0.01$; ***, $P < 0.001$; Student's t -test (T0 vs different times); $n = 3$; bars indicate \pm SE).

rates than in WT, and attained WT concentrations after 2 h of treatment (Fig. 4b). These results were consistent with a 50% reduction in green leaf volatile production in *ir-hpl* plants (Table S4) and therefore with residual HPL activity in these plants. The concentrations of the remaining C_{12} derivatives were also reduced in leaves of *ir-hpl* plants compared with the WT (Fig. S3).

The majority of 9-OH-traumatol is formed from (9Z)-traumatol via NaLOX2 activity

The mechanism of 9-OH-traumatol formation from (9Z)-traumatol in plants has been a matter of controversy, with some results supporting the enzymatic (Gardner, 1998) and others the nonenzymatic biogenesis of this metabolite (Noordermeer *et al.*, 2000). To investigate the mechanism of 9-OH-traumatol formation in *N. attenuata*, equal amounts of proteins from leaf extracts of WT and *ir-lox2* plants were incubated with either (9Z)-traumatol or (10E)-traumatol and the reaction products were analyzed by LC-MS/MS.

Fig. 4 Accumulation of 9-OH-traumatol in leaves of *Nicotiana attenuata* wild-type (WT; triangles), *ir-lox2* (closed circles) and *ir-hpl* (open circles) plants after wounding and fatty acid-amino acid conjugate (FAC) elicitation. Leaves from WT, *ir-lox2* and *ir-hpl* plants were either wounded with a fabric pattern wheel (a) or subjected to wounding plus the addition of 18:3-Glu (b; FAC elicitation). Leaf samples were harvested at different times, extracted and the amounts of 9-OH-traumatol were quantified by liquid chromatography-mass spectrometry/mass spectrometry (LC-MS/MS) (*, $P < 0.05$; **, $P < 0.01$; ***, $P < 0.001$; Student's t -test (WT vs transgenic line at the same time-point); $n = 3$; bars indicate \pm SE).

Consistent with the nonenzymatic formation of 9-OH-traumatol from (9Z)-traumatol (Noordermeer *et al.*, 2000), approximately one-third of *de novo* produced 9-OH-traumatol in WT leaf extracts was generated immediately (first phase: T0) after supplying the substrate; however, the remaining two-thirds required an incubation period of at least 15 min (second phase; Fig. 5a). When leaf extracts of *ir-lox2* plants were supplied with (9Z)-traumatol, the amount of 9-OH-traumatol produced immediately was similar to that in WT leaf extracts; however, the second phase of accumulation was suppressed (Fig. 5a). Consistent with the formation of the major fraction of 9-OH-traumatol by enzymatic mechanisms, the heat inactivation of WT leaf extracts suppressed the accumulation of 9-OH-traumatol (Fig. 5b) and co-incubation of WT leaf extracts with the LOX inhibitor 3,4-dihydroxy-phenylethanol (DHPE) also suppressed its accumulation during the second phase of the reaction (Fig. 5b). When (10E)-traumatol was used as the substrate, *de novo* formation of 9-OH-traumatol in WT

Fig. 5 Analysis of the mechanisms of 9-OH-traumatin formation in leaves of *Nicotiana attenuata* plants. (a) 100 µg of total protein from wild-type (WT; triangles) and ir-lox2 (circles) leaf extracts was incubated in 0.2 ml of reaction buffer supplied with 1 µg of (9Z)-traumatin. (b) 100 µg of total protein from WT leaf extracts were incubated in 0.2 ml of reaction buffer supplied with 1 µg of (9Z)-traumatin. Heat inactivation was achieved by incubating the leaf extracts for 5 min at 95°C before the addition of the substrate. The lipoxygenase inhibitor dihydroxyphenylethanol (DHPE) was added to obtain a final concentration of 10 mM. Triangles, control; closed circles, heat-inactivated; open circles, 10 mM DHPE. (c) 100 µg of total protein from WT (triangles) and ir-lox2 (circles) leaf extracts was incubated in 0.2 ml of reaction buffer supplied with 1 µg of (10E)-traumatin. In all cases the reactions were carried out at room temperature and stopped by the addition of chloroform : methanol. After extraction, 9-OH-traumatin was quantified by liquid chromatography-mass spectrometry/mass spectrometry (LC-MS/MS) (*, $P < 0.05$; **, $P < 0.01$; ***, $P < 0.001$; Student's *t*-test (WT vs genotype or treatment at same time point); $n = 3$; bars indicate \pm SE).

and ir-lox2 leaf extracts was 10 times lower compared with its formation from (9Z)-traumatin (Fig. 5c).

It has been previously shown that the co-incubation of soybean (*Glycine max*) LOX-1 *in vitro* with (3Z)-nonenal and C_{18} hydroperoxides stimulated the activity of this enzyme toward formation of 4-OH-(2E)-nonenal (4HNE) (Gardner & Grove, 1998). To evaluate whether the oxidation of (9Z)-traumatin by NaLOX2 was indirect and depended on the accumulation of C_{18} -hydroperoxides, equimolar amounts of (9Z)-traumatin and C_{18} -hydroperoxides were added to leaf extracts of WT and ir-lox2 plants. The accumulation of 9-OH-traumatin was not affected by the added C_{18} -hydroperoxides (data not shown).

9-OH-traumatin forms conjugates with GSH during the wound and FAC elicitation response

9-OH-traumatin is an oxylipin-RES (Gardner, 1998) and as a soft electrophile it is liable to form Michael-type adducts with, for example, the sulfhydryl groups of abundant nucleophilic targets, such as reduced glutathione (GSH) (Farmer & Davoine, 2007; Mueller & Berger, 2009). GSH is an important intracellular redox buffer that accumulates at 1–5 mM in leaves and controls the concentrations of reactive molecules (Mueller & Berger, 2009). To first evaluate whether 9-OH-traumatin forms adducts with GSH, purified 9-OH-traumatin was incubated *in vitro* with commercial GSH and the reaction products were analyzed by LC-MS/MS. Formation of the 9-OH-traumatin–GSH conjugate occurred *in vitro* and, after 4 h of reaction at room temperature, > 50% of the initial amount of 9-OH-traumatin reacted with GSH (data not shown). To analyze the endogenous formation of this adduct, leaves of WT and ir-lox2 *N. attenuata* plants were wounded and the levels of 9-OH-traumatin-GSH accumulation were quantified (Fig. 6a). In WT plants, 9-OH-traumatin-GSH adducts were < 0.05 nmol g⁻¹ FW in unelicited leaves; however, their concentrations increased rapidly after the treatments to reach *c.* 9 nmol g⁻¹ FW within 1 h (Fig. 6a). In ir-lox2 plants, 9-OH-traumatin-GSH was undetected in unelicited leaves and accumulated at < 0.3 nmol g⁻¹ FW after wounding (Fig. 6a).

9-OH-traumatin is not deposited on the leaf surfaces of *N. attenuata* plants

In addition to conjugation, cells can control the effects of reactive molecules by depositing them outside cells; for example, on the leaf surface. To investigate whether this was the case for 9-OH-traumatin, the surfaces from unelicited and wounded leaves were washed with methanol and both the washes and the surface-washed leaves were analyzed (Fig. 6b). In unelicited leaves, 9-OH-traumatin and 9-OH-traumatin-GSH accumulated primarily in the surface-

Fig. 6 Analysis of the formation of 9-OH-traumatin-glutathione (GSH) adducts and localization of 9-OH-traumatin. (a) Leaves from *Nicotiana attenuata* wild-type (WT; triangles) and *ir-lox2* (circles) plants were wounded with a fabric pattern wheel and leaf samples were harvested at different times, extracted and the amounts of 9-OH-traumatin-GSH adducts were quantified by liquid chromatography-mass spectrometry/mass spectrometry (LC-MS/MS) (***, $P < 0.001$; Student's *t*-test (WT vs *ir-lox2* at the same time-point); $n = 3$; bars indicate \pm SE). (b) Intact and wounded leaves from WT *N. attenuata* plants were washed for 1 min with methanol to extract methanol-soluble surface compounds and both the wash and the remaining surface-washed leaf were used for quantification of C₁₂ molecules (Fig. 1) and 9-OH-traumatin-GSH adducts by LC-MS/MS ($n = 3$; bars indicate \pm SE).

washed leaf, with lower amounts in the wash (time 0; Fig. 6b), while the remaining C₁₂ derivatives were detected at very low levels (< 0.1 nmol g⁻¹ FW) in both fractions (Fig. 6b). At 15 min after wounding, 9-OH-traumatin was recovered from the wash and the surface-washed leaf extract in comparable amounts (≈ 4 nmol g⁻¹ FW) whereas 9-OH-traumatin-GSH was detected in higher amounts (6 vs 1 nmol g⁻¹ FW) in the surface-washed leaf (Fig. 6b). The remaining C₁₂ derivatives were ≈ 2 times more abundant in the leaf extract than in the wash (Fig. 6b). These results suggested that 9-OH-traumatin was retained in the cells and that after wounding it probably became accessible

to methanol through the damaged tissue during the leaf wash.

Formation of 9-OH-traumatin by NaLOX2 activity establishes a major flux for the production of reactive C₁₂ derivatives of the HPL pathway

Calculation of the rates of accumulation of the C₁₂ derivatives of the HPL pathway within 15 min of the wound response showed that on average 1 g of leaf converted 850 pmol min⁻¹ of (9Z)-traumatin to 9-OH-traumatin, with approximately two-thirds of this conversion being

Fig. 7 Proposed model for the biosynthesis and metabolism of C_{12} derivatives of the hydroperoxide lyase (HPL) pathway in *Nicotiana attenuata* leaves. Upon wounding and fatty acid–amino acid conjugate (FAC) elicitation, 18:2 and 18:3 are released from membrane glycerolipids and dioxygenated by lipoxygenase-2 (NaLOX2) to generate 13-hydroperoxides (13-HPODE and 13-HPOTE, respectively). These molecules are substrates for NaHPL which produces C_6 aldehydes and (9Z)-traumatin. Formation of 9-OH-traumatin determines the major flux of C_{12} derivatives in leaves ($850 \text{ pmol min}^{-1} \text{ g}^{-1} \text{ FW}$) and recycling NaLOX2 activity determines two-thirds of this flux ($560 \text{ pmol min}^{-1} \text{ g}^{-1} \text{ FW}$) while the remaining third is determined by the nonenzymatic oxidation of (9Z)-traumatin ($290 \text{ pmol min}^{-1} \text{ g}^{-1} \text{ FW}$). Formation of (2E)-traumatic acid may occur via (10E)-traumatin (not detected) auto-oxidation or isomerization of (3Z)-traumatic acid. The rates of accumulation were calculated based on the amounts of C_{12} molecules generated *de novo* within 15 min of the wound response.

catalyzed by NaLOX2 activity and the remaining one-third nonenzymatically (Fig. 7). It was found that $380 \text{ pmol min}^{-1}$ of the 9-OH-traumatin was conjugated to GSH and the remaining (9Z)-traumatin was converted to (2E)-traumatic acid ($7.9 \text{ pmol min}^{-1}$), (3Z)-traumatic acid ($2.1 \text{ pmol min}^{-1}$) and 12-OH-(9Z)-dodecenoic acid ($1.2 \text{ pmol min}^{-1}$; Fig. 7).

C_{12} derivatives of the HPL pathway induce changes in gene expression

To evaluate the signaling capacity of the C_{12} derivatives of the HPL pathway during the wound response, leaves of plants with reduced expression of NaLOX2 and NaLOX3 (*ir-lox2/ir-lox3*; Kallenbach *et al.*, 2010) were used. In this case, doubly silenced lines were chosen to minimize the effects of endogenously produced C_{12} derivatives and jasmonates after wounding. Thus, *ir-lox2/ir-lox3* plants were wounded with a fabric pattern wheel, and either a 1 : 1 mixture of (9Z)-traumatin : 9-OH-traumatin or solvent (control treatment) was immediately applied to the wounds. In this case, $1 \mu\text{g}$ of each component was applied per leaf; amounts that corresponded to the endogenous amounts produced by leaves after wounding (Fig. 3). Total RNA was extracted from leaves at 120 min after the treatments and used for analysis of gene expression by microarray hybridization (see the Materials and Methods section).

The results of the analysis showed that, after the treatment with C_{12} derivatives, 320 genes showed significant

changes in expression ($-1 > \log_2(\text{fold change}) > 1$; $q\text{-value} < 0.035$; FDR 3.3%) compared with the control treatment, with five genes down-regulated and the remainder up-regulated. A subset of these genes is presented in Table 1 and the complete list of genes in Table S3. Among the genes with known function that were most strongly up-regulated were *N. attenuata* homologs of glutathione *S*-transferase (GST), serine incorporator 1 (SERC1), monodehydroascorbate reductase (MDAR), protein disulfide isomerase (PDI) and a thioredoxin domain-containing protein; genes associated with oxidative stress responses in plants and animals (Table 1; see the Discussion section). Among the up-regulated genes were also four homologs of basic-helix-loop-helix (bHLH)-containing domain transcription factors and homologs of the defense-associated genes *PATHOGENESIS-RELATED PROTEIN 5* (*PR5*), proteinase inhibitor (*PI*) and a disease resistance response gene (Table 1). Among the signaling components, homologs of *ETHYLENE RECEPTOR 1* (*ETR1*), receptor-like protein kinase BRASSINOSTEROID INSENSITIVE 1 (*BRI1*)-like 3 (*BRL3*) and *MITOGEN-ACTIVATED KKK3* (*MKKK3*) were also up-regulated (Table 1). Among the down-regulated genes was BAK1 (BRASSINOSTEROID INSENSITIVE 1-associated receptor kinase 1; Table S3).

Discussion

Understanding the biosynthesis and function of the C_{12} derivatives of the HPL pathway has been a challenge in

plant biology, and efforts initiated to this end a few decades ago have not been pursued with the same impetus as those associated with the C₆ derivatives of this pathway. With the opportunity to use reverse genetic approaches in the unraveling of the biosynthesis and signaling capacities of these molecules, the requirement for a suitable method for their analysis is self-evident. Here, we have described an LC-MS/MS-based approach to quantify C₁₂ derivatives of the HPL pathway and have shown its application in the detection of changes induced by wounding and FAC elicitation in WT plants and by genetic deficiencies of biosynthetic enzymes (i.e. NaLOX2 and NaHPL).

Generation of 9-OH-traumatin in *N. attenuata* leaves

9-OH-traumatin was initially isolated as a product of 13-HPODE in extracts of soybean and alfalfa (*Medicago sativa*) seedlings, and it has been suggested that (9Z)-traumatin is converted to 9-OH-traumatin by LOX activity (Gardner, 1998). A subsequent study showed, however, that 9-OH-traumatin is formed preferentially nonenzymatically

and perhaps indirectly via 13-HPODE formation and not directly by LOX activity towards (9Z)-traumatin (Noordermeer *et al.*, 2000). We observed that approximately one-third of the *de novo* synthesized 9-OH-traumatin was formed nonenzymatically. However, consistent with the proposed LOX-mediated biogenesis of this oxylipin, the production of the remaining two-thirds depended either directly or indirectly on NaLOX2 activity. The reduced capacity of ir-lox2 leaf extracts to produce 9-OH-traumatin after exogenous addition of (9Z)-traumatin, the sensitivity of its production to heat inactivation and to the LOX inhibitor DHPE, and the independence of its accumulation to the presence of C₁₈ hydroperoxides strongly suggested that NaLOX2 directly acts on (9Z)-traumatin to form 9-OH-traumatin. Although it is unlikely, we cannot completely rule out the possibility that the formation of 9-OH-traumatin by this enzyme is indirect via the generation of an oxidative metabolite other than C₁₈ hydroperoxides. We have previously shown that NaLOX2 also oxidizes the fatty acid moiety of the FAC 18:3-Glu to form 13-OOH-18:3-Glu and its derivatives (Vandoorn

et al., 2010). Thus, the range of substrates that this enzyme can use is not restricted to free 18:2 and 18:3 and may include (9Z)-traumatin to generate 9-OH-traumatin, as previously proposed in other systems (Gardner, 1998).

Generation of other low-abundance C₁₂ derivatives of the NaHPL pathway and systemic accumulation

Alcohol dehydrogenase activity reduces the aldehyde groups of (9Z)-traumatin to form 12-OH-(9Z)-dodecenoic acid (Grechkin *et al.*, 1990). The low amounts of this derivative accumulating in wounded and FAC-elicited *N. attenuata* leaves suggest that either this enzymatic activity is very low in this tissue or the rapid oxidation of (9Z)-traumatin to 9-OH-traumatin outcompetes its reduction. The low levels of accumulation of dodecenedioic acids in wounded and FAC-elicited leaves were consistent with the rapid exchange of (9Z)-traumatin from NaHPL to NaLOX2, as the accumulation of dodecenedioic acids remained below 0.02 nmol g⁻¹ FW (Fig. S3).

Even though the concentrations of dodecenedioic acids and 12-OH-(9Z)-dodecenoic acid were much lower than those of 9-OH-traumatin, their accumulation increased rapidly and transiently upon wounding and FAC elicitation (Fig. 3b). Thus, a possible scenario is that, as previously demonstrated for different plant responses (English & Bonner, 1937; Bonner & English, 1938; Ivanova *et al.*, 2001), these molecules may work as signals during the responses of *N. attenuata* to wounding and herbivory.

In distal leaves, the concentrations of the C₁₂ metabolites did not change significantly within 2 h after wounding and FAC elicitation; however, we cannot exclude the possibility that some of these derivatives are vascularly transported in small amounts to distal leaves. It has been recently shown that azelaic acid, a saturated C₉ dicarboxylic acid, accumulates in the sap of *Arabidopsis thaliana* and confers local and systemic resistance against *Pseudomonas syringae* (Jung *et al.*, 2009).

The role of C₁₂ derivatives as potential signaling molecules acting during the response to wounding and herbivory

9-OH-traumatin accumulated to *c.* 2 nmol g⁻¹ FW in unelicited WT leaves, probably reflecting a basal flux of 18:2 and 18:3 through NaLOX2 and NaHPL in this tissue and the cellular tolerance to small amounts of this oxylipin RES. This basal flux was also reflected in the basal production of C₆ volatiles in WT plants (Table S4). The effect of oxylipin RES in cellular processes has been well documented in both plants and animals. For example, they can negatively affect cellular metabolism by the chemical modification of enzymes or by reducing photosynthetic rates (Almeras *et al.*, 2003; Mueller & Berger, 2009). At the level of gene expression,

oxylipin RES can induce the transcription of genes related to detoxification, stress responses and secondary metabolism (Bate & Rothstein, 1998; Vollenweider *et al.*, 2000; Almeras *et al.*, 2003; Weber *et al.*, 2004; Mueller *et al.*, 2008). Thus, one possibility is that 9-OH-traumatin plays a role in the wound and herbivore responses through its RES properties; for example, by the activation of cell protection genes (Farmer & Davoine, 2007). After wounding, 38% of *de novo* synthesized 9-OH-traumatin conjugated to GSH, indicative of a strict control of its accumulation above certain levels, probably to prevent cytotoxic effects. The formation of oxylipin RES conjugates with GSH has been observed during the hypersensitive response (HR) induced by cryptogin elicitation in tobacco leaves (Davoine *et al.*, 2006) and it has been proposed that the generation of these conjugates may play a direct role in signaling; for example, by the alteration of the cellular redox balance (Meyer & Hell, 2005; Mullineaux & Rausch, 2005; Ogawa, 2005; Davoine *et al.*, 2006). Thus, an additional possibility is that the conjugation of 9-OH-traumatin to GSH plays a signaling role during the responses of *N. attenuata* to wounding and herbivory.

Consistent with the potential signaling roles of C₁₂ derivatives of the HPL pathway during the wound response, gene expression analysis by microarrays showed that these derivatives have the capacity to exert changes in the expression of 320 genes. Among the top 12 most up-regulated transcripts (> 4-fold at 120 min) were several involved in responses to oxidative stress and protein chemical modification; a result consistent with 9-OH-traumatin being sensed as an RES by cells. These transcripts corresponded to GST (an enzyme that conjugates GSH to electrophilic centers on a wide variety of substrates, including peroxidized lipids and RES), MDAR (a component of the GSH-ascorbate antioxidant system; Dinakar *et al.*, 2010), PDI (an enzyme involved in the formation of disulfide bonds in chloroplasts; Wittenberg & Danon, 2008) and SERC1 (an enzyme involved in the protein mis-folding response in the ER-Golgi system; Aoki *et al.*, 2002). Interestingly, the expression of four transcription factors (TFs) corresponding to the bHLH family were induced by C₁₂ derivatives (Table 1). This family of TFs contains the well-characterized Myelocytomatosis transcription factor (MYC)2, 3 and 4 which are involved in the regulation of defense responses in plants (Niu *et al.*, 2011). These results suggested that these TFs could also participate in the mediation of responses induced by C₁₂ derivatives. In summary, the effect of these derivatives on the expression of 320 genes encoding proteins involved in diverse cellular processes including defense (e.g. PR5 and PI), signaling (e.g. ETR1, MKKK3 and BRLK3) and redox homeostasis (e.g. GST, MDAR and PDI; Tables 1, S3) provided strong evidence for the contribution of C₁₂ derivatives of the HPL pathway to the control of plant responses to wounding and probably herbivory in *N. attenuata*. Future work will focus on

disentangling the potential specific roles of 9-OH-traumatin, 9-OH-traumatin-GSH, 12-OH-(9Z)-dodecenoic acid and dodecenedioic acids in the regulation of responses to wounding and herbivory and on the mechanisms underlying the formation of 9-OH-traumatin from (9Z)-traumatin by NaLOX2.

Supporting figures

Figure S1. Auto-oxidation of (9Z)-traumatin *in vitro*

A solution of (9Z)-traumatin in methanol was air-dried at room temperature for 2 hours. After reconstituting the sample in methanol, the products were reduced with excess NaBH₄ and derivatized with diazomethane and MSTFA. The derivatized products were analyzed by GC-MS. Formation of 9-OH-traumatin and 11-OH-traumatin as auto-oxidation products was detected, consistently with Noordermeer *et al* (2000).

Chapter 5

Figure S2. Determination of the linearity and limit of detection (LoD) for C_{12} metabolites. Commercial standards and synthetic compounds were spiked at different concentrations in leaf-derived matrix obtained from ir-lox2 plants. Samples were analyzed by LC-MS/MS in the negative MRM mode and the peak areas corresponding to each analyte were integrated and plotted against the amount of analyte injected in the column (ng in column).

Figure S3. Accumulation of C₁₂ derivatives in leaves of WT, ir-lox2 and ir-hpl plants after wounding and FAC elicitation

Leaves from WT, ir-lox2 and ir-hpl plants were either wounded with a fabric pattern wheel (a) or wounded plus the addition of 18:3-Glu (b; FAC elicitation). Leaf samples were harvested at different times, extracted and the amounts of C₁₂ derivatives were quantified by LC-MS/MS (*: $P < 0.05$, **: $P < 0.01$, ***: $P < 0.001$, Student's t-test (WT vs transgenic line at same time point), $n=3$, bars indicate SE).

Chapter 5

Figure S4. Calibration curves for C_{12} standards.

Different amounts of C_{12} standards were spiked in leaf extracts (matrix) from ir-lox2 plants and analyzed by LC-MS/MS using the parameters described in Material and Methods. Units in the Y and X axis are peak areas ($\times 10^6$).

Figure S5. Quantification of NaHPL mRNA levels in WT and ir-hpl plants.

Total RNA was extracted from leaves of either WT or ir-hpl (lines 425 and 428) plants before (control) and 45 min after wounding and OS elicitation. The abundance of NaHPL transcripts was analyzed by qPCR using Na*Actin* mRNA as a reference. NaHPL mRNA levels represent the relative levels to the reference gene (Bars represent \pm SE, $n=5$).

Figure S6. Southern blot analysis of ir-hpl plants.

Genomic DNA was isolated from WT and ir-hpl (lines 425 and 428) plants, digested with EcoRV and separated by agarose-gel electrophoresis using standard conditions (see Appendix S1 for methodological details). A gene-specific probe corresponding to the hygromycin resistance gene (*hptII*) was labeled with [α - 32 P] dCTP and used for hybridization. The arrow points to the single T-DNA insertions in ir-hpl lines.

Appendix S1. Characterization of ir-hpl plants

Materials and Methods

Generation of transgenic ir-hpl lines

Transgenic *N. attenuata* (ir-hpl) plants reduced in the expression of NaHPL were generated via leaf disc *Agrobacterium*-mediated transformation and seedling regeneration as previously described (Krügel *et al.*, 2002). The binary vector used for plant transformation was pSOL3 (Bubner *et al.*, 2006) engineered to carry a fragment of the NaHPL cDNA (GenBank accession: AJ414400) subcloned in inverted repeat orientation (vector pSOL3HPL). T₁ transformed plants were analyzed by quantification of NaHPL mRNA levels by real-time quantitative PCR in unelicited leaves and in leaves elicited with *Manduca sexta* oral secretions (OS) and for T-DNA single insertion by Southern blot hybridization (see below). Segregation analysis of hygromycin resistance in T₂ seedlings was performed on agar plates supplemented with hygromycin (0.025 mg mL⁻¹). Two lines, ir-hpl 425-4 (425) and 428-8 (428) showed the lowest levels of NaHPL mRNA accumulation (Figure AS1) and had a single T-DNA insertion in their genomes (Figure AS2).

For Southern blot analysis, genomic DNA of the WT and ir-hpl lines was isolated by the cetyltrimethylammonium bromide (CTAB) method. DNA samples (10 µg) were digested with EcoRV overnight at 37 °C according to commercial instructions and separated on a 0.8% (w/v) agarose gel using standard conditions. DNA was blotted onto Gene Screen Plus Hybridisation Transfer membranes (Perkin Elmer Life and Analytical Sciences, Boston, MA, USA) using the capillary transfer method. A gene-specific probe for the hygromycin resistance gene *hptII* was generated by PCR using the primer pairs HYG1-18 (5'-CCGGATCGGACGATTGCG-3') and HYG3-20 (5'-CGTCTGTCGAGAAGTTTCTG-3'). The probe was labeled with [α -³²P]dCTP (Perkin Elmer) using the Rediprime II kit (Amersham Pharmacia) according to commercial instruction.

Plant treatments

Leaf wounding was performed by rolling three times a fabric pattern wheel on each side of the midvein of 40-day-old rosette stage plants. For a wounding + water (w+w) treatment, 20 µL of deionized water were immediately pipetted onto the wounded leaf. For a wounding + oral secretions (w+OS) treatment, 20 µL of *Manduca sexta* oral secretion (diluted 1:3 in water, v/v) was applied to the wounds. Samples from untreated plants were used as controls.

Chapter 5

Volatile collection and analysis

Single leaves (+1 position) of wild type and ir-hpl plants (n=6 per genotype and treatment) were enclosed immediately after treatment between two 50 mL food-quality plastic containers (Huhtamaki, Bad Bertricher, Germany) secured with miniature claw-style hair clips. Ambient air was pulled through the collection chamber and a glass tube (ARS, Inc., Gainesville, FL, USA) packed with glass wool and 20 mg of Super Q (Alltech, Düsseldorf, Germany). Airflow was created by a vacuum pump (model DAA-V114-GB; Gast Mfg; Benton Harbour, MI, USA) at ~200 mL min⁻¹. SuperQ traps were eluted with 250 µL dichloromethane into a GC vial containing a glass insert after spiking each trap with 400 ng tetralin (Sigma-Aldrich, Germany) as an internal standard. Samples were analyzed on an Agilent 6890N gas chromatograph equipped with an Agilent 7683 autoinjector (Agilent Technologies, Böblingen, Germany) and coupled with a LECO Pegasus III time-of-flight mass spectrometer with a 4D thermal modulator upgrade (LECO, Mönchengladbach, Germany) as described by Gaquerel et al. (2009). GLVs were identified and quantified using standard solutions of (3Z)-hexenal, (2E)-hexenal, (3Z)-hexenol, (2E)-hexenol, (3Z)-hexenyl-acetate, (2E)-hexenyl-acetate, (3Z)-hexenyl-propanoate, (3Z)-hexenyl-butanoate, (2E)-hexenyl-butanoate (Sigma-Aldrich, Germany) and (2E)-hexenyl-propanoate (Bedoukian Research Inc, Danbury, USA).

Quantitative real-time PCR assay

Total RNA was extracted from single leaves (+2 position) of WT and ir-hpl plants with TRI Reagent (Sigma-Aldrich, Germany) according to the manufacturer's instruction. Reverse transcription of 1 µg of total RNA was performed using SuperScript II Reverse Transcriptase (Invitrogen, Germany) and a poly-T primer. Quantitative real-time PCR (ABI PRISM™7000, Applied Biosystems, Foster City, CA, USA) was conducted with 40 ng cDNA using the qPCR™ core reagent kit (Eurogentec, Köln, Germany) and NaHPL-specific primer pairs (FP: 5' CACTTAGACTTAGTCCACCTGTGC 3', RP: 5' AACACAACTTTTCAGGATCATCA 3'). The PCR products were detected by gene-specific double fluorescent dye-labeled TaqMan® probes (Probe: 5' TCAGCCATTGGTAATGAGAGATCCAAAGG 3'). For calibration we used a duplicated dilution series of cDNAs which had been transcribed from induced RNA samples of the same experiment and calculated the relative transcript abundance by efficiency-correcting for each primer pair and normalizing to the *N. attenuata* actin gene (FP: 5' GGTCGTACCACCGGTATTGTG 3', RP: 5' GTCAAGACGGAGAATGGCATG 3', Probe: 5' TCAGCCACACCGTCCCAATTATGAGG 3').

Chapter 6: Discussion

Identification of the early mediators of the FAC signal transduction pathway

Recent years have brought progress in the elucidation of early signaling events triggered after herbivore perception; however, the molecular mechanisms through which plants decode insect feeding are still largely unknown. Recently, the advent of new quantitative techniques for gene expression profiling and high throughput sequencing capacity has made it possible to explore the genome-wide changes occurring in the transcriptome of plants for which little nucleotide sequence information is currently available in public databases. I used the SuperSAGE technique to identify the molecular components triggering insect-specific responses in *Nicotiana attenuata* after perception of the main elicitors present in *Manduca sexta* OS: fatty acid-amino acid conjugates (FACs). I analyzed the changes in the expression of thousands of genes in *N. attenuata* leaves after perception of the FAC 18:3-Glu.

Two SuperSAGE libraries were generated from FAC-induced leaf samples (F library) and wounded leaf samples (W library) with the goal of identifying transcripts that were rapidly and differentially regulated by FACs. A total of 354,930 tags were sequenced from which 12,774 unique transcripts (UniTags) were identified. I analyzed the statistically significant changes in tag copy number between the F and W libraries and identified 547 differentially regulated UniTags (P -value < 0.05 ; $FC \geq 2.5$ for up-regulated UniTags and $FC \leq 0.4$ for down-regulated UniTags). Among these UniTags, 430 were up-regulated and 117 down-regulated after 18:3-Glu elicitation compared to wounding. Sixty percent of the differentially expressed UniTags could be assigned to a protein entry in GenBank and UniProtKB/TrEMBL protein databases. The remaining UniTags could not be annotated, most likely because the SuperSAGE tags are derived from the 3' UTR of each mRNA molecule: since most of the *Nicotiana* spp nucleotide entries in GenBank correspond to *N. tabacum*, some mismatches may be attributed to polymorphisms in the 3' UTR of mRNAs from *N. attenuata* and this tobacco species.

Chapter 6

Gene Ontology (GO) was used to assign gene function categories and the analysis disclosed a total of 75 UniTags with potential regulatory function. Among these were 22 protein kinases and 30 transcription factors. The remaining UniTags with putative regulatory function belonged to the GO classes protein phosphatase, signal transduction and nucleic acid binding. As a validation method, I quantified the mRNA levels corresponding to 27 UniTags by qPCR and validated the data obtained by SuperSAGE for 20 UniTags.

The biological relevance of seven selected putative regulatory components was analyzed by virus induce gene silencing (VIGS). Three putative regulatory components of resistance mechanisms against lepidopteran larval feeding were identified: a lipid phosphate phosphatase (LLP), a protein of unknown function (Unk-A) and a lectin receptor-like kinase (LecRK1). Interestingly, the mass gain observed in *M. sexta* larvae feeding on NaUnk-A, NaLPP and NaLecRK1-silenced plants was more than 2-fold the mass gain by larvae fed on control EV plants. Since a large number of defense-related genes are regulated by JA and JA-Ile, the levels of these phytohormones were quantified after wounding and wounding plus 18:3-Glu elicitation. Compared to EV control plants, NaLPP-silenced plants displayed significantly reduced JA and JA-Ile accumulation after 18:3-Glu elicitation. This reduction in JA and JA-Ile could result in impaired defense responses against *M. sexta* herbivory in NaLPP-silenced plants. Plants silenced in NaUnkA expression had similar levels of JA and JA-Ile accumulation compared to EV control plants after 18:3-Glu elicitation. These results indicated that *M. sexta* larval performance was not the result of impaired JA biosynthesis in NaUnkA-silenced plants and thus suggested that another mechanism acting independently of JA and JA-Ile regulates defense responses in *N. attenuata*. The exact molecular mechanisms regulated by NaLPP and NaUnkA are still unknown.

NaLecRK1: a novel lectin receptor-like kinase involved in the regulation of *Nicotiana attenuata*'s defense responses against *Manduca sexta*

In the SuperSAGE analysis, I identified a receptor-like kinase (NaLecRK1), which is rapidly induced after wounding and OS of *M. sexta* or FAC treatment and, when silenced

Chapter 6

by virus induced gene silencing (VIGS) or inverted repeated RNA interference in *N. attenuata* plants (ir-lecRK1 plants), substantially increased *M. sexta* larval performance. These results encouraged me to fully characterize the role of NaLecRK1 in the FAC signal transduction pathway and defense responses against insects. Based on sequence similarity and according to the current classification of lectin receptor-like kinases (LRKs; Bouwmeester and Govers, 2009), NaLecRK1 belongs to the G-type LRK class. Previous studies have associated some G-type LRKs with defense responses against pathogens. For example, NgRLK1 from *N. glutinosa* and NbLRK1 from *N. benthamiana* interact with the extracellular proteins (elicitors) from *Phytophthora capsici* fungi (Kim et al., 2010) and *P. infestans* (Kanzaki et al., 2008), respectively. Also, in rice the LRK Pi-d2 confers resistance to *Magnaporthe grisea* fungi (Chen et al., 2006). NaLecRK1 displayed amino acid sequence to NgRLK1, NbLRK1 and Pi-d2, which suggest that NaLecRK1 may also participate in the pathogen response.

In *N. attenuata*, one of the earliest events differentially induced by OS and FACs compared to wounding is the activation of the protein kinases WIPK and SIPK (Wu et al., 2007). Activation of these protein kinases takes place immediately after wounding and is augmented several-fold by additional supply of *M. sexta* OS (Wu et al., 2007). In this study, I evaluated the dependence of NaLecRK1 mRNA regulation on WIPK and SIPK. I found that silencing of SIPK and WIPK (ir-sipk and ir-wipk) largely abolished the transcriptional activation of NaLecRK1 after 18:3-Glu elicitation, suggesting a positive regulation of SIPK and WIPK in NaLecRK1 transcriptional regulation. A JA burst also occurs upon *M. sexta* herbivory in *N. attenuata* (Halitschke et al., 2001), thus I also evaluated the transcriptional regulation of NaLecRK1 in plants deficient in JA biosynthesis or perception and found that jasmonates inhibit the induction of this gene. These results revealed that the induction of NaLecRK1 expression is under tight temporal control; it is induced by OS/FAC elicitation but the levels of induction are checked by JA, which is produced following OS/FAC elicitation.

In *N. attenuata*, responses to *M. sexta* herbivory and OS or FAC elicitation overlap by 80% (Halitschke et al., 2001) and include changes in the expression of more than 500 genes, 90 proteins, 170 primary and secondary metabolites and the differential production

Chapter 6

of JA, ET and SA (Hermsmeier et al., 2001; Giri et al., 2006; Gaquerel et al., 2010; Kallenbach et al., 2010). JA and JA-Ile play essential roles in mediating plant responses to chewing arthropods (Wang et al., 2007; Howe and Jander, 2008), whereas SA coordinates the elicitation of defense responses against biotrophic pathogens (Ryals et al., 1996; Rivas-San Vicente and Plasencia, 2011) and in herbivore defense responses, SA antagonizes JA induced defenses (Diezel et al., 2009). When *NaLecRK1* expression is silenced (*ir-lecRK1* plants), elicitation of *ir-lecRK1* leaves by *M. sexta* OS and larval folivory induced the accumulation of SA to levels 2-fold higher than those in WT plants. This suggests that *NaLecRK1* expression negatively controls the amount of SA produced by *N. attenuata* upon herbivory and thereby the differential induction of defense responses (see below).

As introduced in chapter 1, *N. attenuata* plants possess a broad arsenal of defense metabolites known to interfere with larval growth and fitness, including 17-hydroxygeranyllinalool diterpene glycosides (HGL-DTGs), nicotine, phenylpropanoid-polyamine conjugates and protease inhibitors (PIs). In tomato (*Solanum lycopersicum*) and *N. attenuata*, the induction of threonine deaminase (TD) is also a critical induced defense response (Chen et al., 2005; Kang et al., 2006). Threonine deaminase (TD) catalyzes the formation of Threonine (Thr) to α -ketobutyrate in the isoleucine (Ile) biosynthetic pathway. In *N. attenuata* reduced *NaTD* expression compromises the levels of JA-Ile formation in leaves and thereby the induction of defense responses (Kang et al., 2006). In tomato, loss of the regulatory domain of TD deaminates Thr in the gut of *M. sexta* larvae and thereby reduces the ingested levels of this essential amino acid (Chen et al., 2005). When *N. attenuata* plants are compromised in the accumulation of HGL-DTGs (Jassbi et al., 2008) or nicotine (Steppuhn et al., 2004), or in the expression of TPI (Zavala et al., 2004) or *NaTD* (Kang et al., 2006), *M. sexta* larvae feeding on these plants gain more mass than larvae feeding on WT plants. Consistent with these previous studies, an increased performance of *M. sexta* larvae on *ir-lecRK1* plants was accompanied by reductions in the induced accumulation of HGL-DTGs, TPIs, nicotine, and *NaTD* expression.

The specificity of a defense response to a particular attacker is the result of fine-tuned interplay among signal transduction pathways. In *N. attenuata*, the production of

Chapter 6

defense secondary metabolites against *M. sexta* is mainly regulated by JA and JA-Ile and modulated by the action of SA and ET (Diezel et al., 2009; Leon-Reyes et al., 2009; Pieterse et al., 2009). Previous studies have pointed to a dose-dependent antagonism of SA on JA-mediated herbivore defenses (Doares et al., 1995; Diezel et al., 2009; Pieterse et al., 2009; Smith et al., 2009). In this study, I quantified the levels of JA, JA-Ile, SA and ethylene accumulation in order to evaluate whether silencing *NaLecRK1* expression affects the biosynthesis of these phytohormones and consequently influences the accumulation of secondary metabolites. The results showed reduced levels of JA-Ile after OS elicitation which, in line with previous studies (Kang et al., 2006; Steppuhn et al., 2004; Zavala et al., 2004; Heiling, Schuman et al., 2010) could lead to lower accumulation of HGL-DTGs, nicotine, or TPI, or *NaTD* expression. However, the 2-fold increase in SA levels as compared to WT levels of JA-Ile after *M. sexta* herbivory on *ir-lecRK1* plants, led to the hypothesis that reduced levels of nicotine, HGL-DTGs, TPI, and *NaTD* expression were the result of SA-mediated suppression of JA and JA-Ile induced defense responses. To test this hypothesis, we generated *N. attenuata* plants ectopically expressing a bacterial *nahG* gene (*ov-nahg*) that were able to deplete endogenous SA levels. To reduce the SA levels in *ir-lecRK1* plants, the *ov-nahg* plants were crossed with *ir-lecRK1* plants to generate *ir-lecRK1xov-nahG* plants. The reduction of SA levels in *ir-lecRK1xov-nahG* plants was sufficient to recover the defense response as shown by *M. sexta* larval performance assays in which larvae performed similar in WT, *ov-nahg* and *ir-lecRK1xov-nahG*. Upon quantification of the accumulation of defense secondary metabolites, I found that the total HGL-DTG levels and TPI activity were fully recovered in *ir-lecRK1xov-nahG* plants, suggesting that the accumulation of these compounds was suppressed by SA in *ir-lecRK1* plants. In contrast, nicotine levels were only partially recovered in *lecRK1xov-nahG* plants compared to WT plants. This partial recovery could be explained by the fact that nicotine levels were significantly reduced by 15% in *ov-nahG* plants compared to WT, indicating that the ectopic expression of *nahG* negatively affects nicotine accumulation. *NaTD* expression was also partially recovered in *ir-lecRK1xov-nahG* plants compared WT. As *NaTD* expression levels were similar between WT and *ov-nahG* plants, this partial recovery was probably the result of a partial involvement of the OS-elicited SA burst in the suppression of *NaTD* expression in *ir-lecRK1* plants.

Chapter 6

In summary, these results demonstrated that the suppression of the OS/*M. sexta*-elicited SA burst in *ir-lecRK1* plants decreased the performance of *M. sexta* larvae. This suppression was sufficient to fully restore the induced accumulation of HGL-DTGs and TPI activity and to partially restore the induced accumulation of nicotine and Na*TD* expression in *ir-lecRK1* plants to WT levels. We concluded that NaLecRK1 negatively regulates the SA burst, allowing the unfettered elicitation of JA-mediated defenses.

Analysis of C₁₂ derivatives of the HPL pathway.

The hydroperoxide lyase (HPL) pathway in plants uses 13-hydroperoxy derivatives of polyunsaturated C₁₈ fatty acids to produce C₆ aldehyde volatiles and unsaturated C₁₂ ω -oxo-acids (12-oxo-9Z-dodecenoic acid or (9Z)-traumatin). In recent years, research has been extensively exploring the metabolism and function of C₆ volatiles with relatively less attention placed on the metabolism and function of C₁₂ acids. One of the first products of the HPL pathway is the formation of (9Z)-traumatin which is then oxidized to yield 9-OH-traumatin. The mechanism of formation of 9-OH-traumatin has been controversial, with some results pointing to an enzymatic conversion (Gardner, 1998) and others supporting a non-enzymatic biogenesis (Noordermeer et al., 2000). Our results were in agreement with both mechanisms: one-third of *de novo* produced 9-OH-traumatin originated non-enzymatically and the remaining two-thirds originated enzymatically in a mechanism dependent indirectly or directly on NaLOX2 activity. 9-OH-traumatin is a reactive electrophile species (RES) which forms Michael-type adducts with the sulfhydryl group of reduced glutathione (GSH; Farmer and Divoine, 2007; Mueller and Berger, 2009). The formation of oxylipin RES conjugates with GSH has been observed during the hypersensitive response (HR) induced by the fungal elicitor cryptogein in tobacco leaves (Divoine et al., 2006), and it has been proposed that the generation of these conjugates may play a direct role in signaling. One possibility is that 9-OH-traumatin conjugated to GSH plays signaling roles in *N. attenuata*'s responses to wounding and herbivory. The precursor (9Z)-traumatin is additionally converted to (2E)-traumatic acid, and then into (3Z)-traumatic acid and 12-OH-(9Z)-dodecenoic acid.

Chapter 6

The signaling role of the C₁₂ derivatives was assessed by gene expression analysis using microarrays. A total of 320 genes were differentially regulated by C₁₂ derivatives, among them several involved in oxidative stress and protein chemical modification. Additionally, transcription factors involved in plant defense responses (MYC transcription factors) and signaling genes have been identified. These results strongly suggested that the C₁₂ derivatives of the HPL pathway play a role in *N. attenuata*'s response to wounding and probably to herbivory as well.

Summary

Summary

Plants have evolved sophisticated mechanisms to specifically recognize attacker-derived molecules and respond consequently. *Nicotiana attenuata* is an annual fire-chasing plant native to the Great Basin desert of the southwestern USA which has evolved a plethora of induced responses against a large number of generalist and specialist herbivore species. *N. attenuata* identifies the nature of the attacker by recognizing elicitors present in the herbivore oral secretions (OS). The hornworm *Manduca sexta* is often the main insect defoliator of *N. attenuata* plants, and the most potent elicitors present in its OS are fatty acid-amino acid conjugates (FACs). The presence of FACs is necessary and sufficient for the elicitation of jasmonic acid (JA) and ethylene (ET) production, triggering the accumulation of secondary metabolites, and for most of the herbivore-induced transcriptional changes and metabolic responses. The mechanism by which plants perceive FACs and activate signal transduction mechanisms to induce these specific defense responses remain at present largely unknown.

In order to unravel these mechanisms, in this thesis I investigated the early cellular events triggered by FACs in *N. attenuata* leaves. For this purpose, SuperSAGE was used to find early transcriptional targets of the FAC signal transduction pathway with the goal of identifying regulatory components of insect mediated responses. I generated two SuperSAGE libraries from FAC-elicited and wounded (control) leaf samples for the identification of transcripts rapidly and differentially regulated by FACs. From 12,744 unique transcript sequences identified (UniTags), 429 and 117 were significantly up- and down-regulated ≥ 2.5 -fold, respectively, after 18:3-Glu elicitation compared to wounding. Based on gene ontology classification, more than 25% of the annotated UniTags corresponded to putative regulatory components. qPCR analysis confirmed the FAC regulation of 70% of a subset of 27 UniTags selected. Seven FAC-regulated genes were functionally characterized by VIGS and three, a G-type lectin receptor-like kinase (LecRK1), a putative lipid phosphate phosphatase (LPP) and a protein of unknown function (UnkA), were identified as important mediators of the *M. sexta*-*N. attenuata* interaction.

Summary

I characterized the G-type lectin receptor-like kinase (*NaLecRK1*) gene in more detail. Silencing the expression of *NaLecRK1* by VIGS or RNAi (*ir-lecRK1* plants) highlighted its importance in the regulation of the defense response to *M. sexta* herbivory. *M. sexta* larvae fed on *ir-lecRK1* plants were 40 to 100% larger than those fed on WT plants, and this corresponded to a several-fold reduction in the accumulation of jasmonate-mediated defense metabolites such as nicotine, 17-hydroxygeranyllinalool diterpene glycosides (HGL-DTGs) and trypsin protease inhibitors (TPI) or *NaTD* expression. The production of jasmonic acid (JA) and jasmonyl-isoleucine (JA-Ile) was unaffected during *M. sexta* herbivory in *ir-lecRK1* plants; however, the production of salicylic acid (SA) was twice that in WT plants. Suppression of the SA burst by introgression of the *nahG* gene into *ir-lecRK1* plants demonstrated that the increased OS-elicited SA formation was responsible for the inhibition of nicotine, HGL-DTG and TPIs accumulation and *NaTD* expression, as well as for the enhanced performance of *M. sexta* larvae on these plants.

I also contributed to the understanding of the biogenesis and function of the C₁₂ derivatives of the HPL pathway in *N. attenuata* plants after wounding and herbivory, as well as a functional understanding of the role of these C₁₂ derivatives in plant responses to wounding and herbivory.

Zusammenfassung

Zusammenfassung

Pflanzen haben ausgeklügelte Mechanismen entwickelt um herbivoren-spezifische Substanzen zu erkennen und dementsprechend auf eine Attacke zu reagieren. *Nicotiana attenuata*, eine einjährige Pflanze beheimatet im Südwesten der USA, muss sich gegen eine Vielzahl verschiedener Pflanzenfresser verteidigen und hat deshalb vielfältige induzierbare Verteidigungsmechanismen entwickelt. Die Identität des jeweiligen Angreifers indentifiziert *N. attenuata* indem die Pflanze spezielle Moleküle aus dem Oralsekret (OS) wahrnimmt. Einer der wichtigsten Frassfeinde von *N. attenuata* ist die Raupe des Tabakswärmers *Manduca sexta*. Das Oralsekret von *M. sexta* enthält verschiedene Fettsäure-Aminosäure-Konjugate (FACs) und diese FACs sind in der Lage, die Biosynthese und Akkumulation von Jasmonsäure (JA) und Ethylen (ET) in der Pflanze auszulösen. JA und ET steuern ihrerseits die Akkumulation von Sekundärmetaboliten. Desweiteren wird durch FACs eine herbivoren-spezifische Expression von Verteidigungsgenen ausgelöst sowie weitere metabolische Veränderungen. Allerdings ist es zum jetzigen Zeitpunkt größtenteils unbekannt, wie Pflanzen FACs erkennen und dadurch Signal-transduktionsmechanismen aktivieren um die spezifischen Verteidigungsreaktionen zu induzieren.

Um die oben genannte Abläufe in der Pflanze besser zu verstehen, habe ich in dieser Arbeit die früheren, durch FACs ausgelösten zellulären Ereignisse in *N. attenuata* Blättern untersucht. Zu diesem Zweck wurde die SuperSAGE Technologie verwendet, die es ermöglicht, frühe transkriptionelle Ziele des FAC Signaltransduktionsweges zu identifizieren. Ziel dieser Technik ist die Identifizierung von regulatorischen Komponenten der durch Insekten ausgelösten Reaktionen. Ich habe hierzu zwei SuperSAGE Bibliotheken, von entweder nur verwundeten oder zusätzlich FAC induzierten Blattproben erstellt, um Transkripte zu identifizieren, die unverzüglich und spezifisch von FACs reguliert werden. Von 12.744 identifizierten Transkriptsequenzen (UniTags) zeigten in FAC induzierten Proben 429 signifikant erhöhte Transkription ($\geq 2,5$ -fach) und 117 signifikant verminderte Transkription ($\leq 0,4$ -fach) im Vergleich zu ausschliesslich verwundeten Blattproben. Mehr als 25% der annotierten Unitags entsprachen, basierend auf Genontology, putativen regulatorischen Komponenten. Eine qPCR Analyse bestätigte die

Zusammenfassung

FAC basierte Regulation von 70% der 27 ausgewählten UniTags. Sieben FAC-regulierte Gene wurden in *N. attenuata* mithilfe von „virus-induced-gene-silencing“ (VIGS) untersucht und drei dieser Gene, eine G-Typ Lectin rezeptor-ähnliche Kinase (LecRK1), eine mutmassliche Lipid Phosphat Phosphatase (LPP) und ein Protein mit unbekannter Funktion (UnkA), wurden als wichtige Mediatoren der *M. sexta*-*N. attenuata* Interaktion identifiziert.

Anschließend habe ich die G-Typ Lectin rezeptor-ähnliche Kinase (LecRK1) detaillierter charakterisiert. Die Verminderung der Transkription von LecRK1 in *N. attenuata* (NaLecRK1), entweder mithilfe von VIGS oder „inverted-repeat-RNA-interference“ (ir-*lecRK1* Pflanzen), hob die Wichtigkeit von NaLecRK1 in der Regulierung von Abwehrmechanismen gegen *M. sexta* Attacken hervor. *M. sexta* Raupen, die auf ir-*lecRK1* Pflanzen fraßen, wurden 40% - 100% größer als Raupen die zur gleichen Zeit auf Wildtyp (WT) Pflanzen fraßen. Dies resultierte aus der in ir-*LecRK1* verminderten Akkumulierung von Verteidigungssubstanzen, wie beispielsweise Nikotin, glykosidische Diterpene (HGL-DTGs), Trypsin-proteinase-inhibitoren (TPI), oder verminderte Expression von NaTD. Die Synthese von JA und JA-isoleucin (JA-Ile) wurde während *M. sexta* Fraß in ir-*lecRK1* Pflanzen nicht beeinflusst, jedoch zeigte sich in Vergleich zu WT Pflanzen eine 2-fach erhöhte Salizylsäure (SA)-synthese. Durch die Unterdrückung der SA Akkumulierung durch Introgression des *nahG* Gens in ir-*lecRK1* Pflanzen konnte ich zeigen, dass die durch *M. sexta* OS induzierte SA-produktion die Ursache für die oben genannten Unterschiede zu WT Pflanzen war.

Desweiteren habe ich geholfen, die Biogenese und Funktion der nach Pflanzenverwundung und –herbivorie durch HPL produzierten C₁₂-Derivate in *N. attenuata* zu untersuchen. Wir untersuchten die Funktion dieser C₁₂ Derivate während der Reaktion der Pflanze auf Verwundung und Herbivorie.

Acknowledgements

I would like to express my gratitude to all those who gave me the possibility to complete this thesis, especially to:

- Prof Ian T. Baldwin for his guidance and support during my entire PhD.
- Dr. Gustavo Bonaventure for his kind supervision, guidance and constant support throughout my PhD.
- DAAD for founding.
- All other lab members of department of Molecular ecology, who have helped in one way or the other. Especially to all Lab 17 members for the nice working atmosphere and for eating my stony-cakes.
- GUBO group members for the fruitful discussions.
- Our Molecular and Analytical Team. Especially to Antje Wissgott for teaching me how to transform *N. attenuata*.
- Danny and Celi for their help in the field season.
- Dr. Tamara Krügel, Andreas Schünzel and all the gardeners for providing me with a lot of plants. Tamara I will really miss your green hands.
- Dr. Karin Groten for her invaluable help and huge patience.
- Martin Niebergall for fixing my computer even when was a matter of turning it on and off.
- Dr. Emmanuel Gaquerel for introducing me in the world of Metabolomics
- My proofreading team and counseling team: Merry, Rohit, Vari and Mari. And Mario for writing the Zusammenfassung.

But my last 4 years would have been empty if weren't for:

- The Schnapps Leute and the Movie night people.
- Ich danke meinen lieben Nachbarn, den Gallas, die mich wie ein Familienmitglied behandelt haben.
- My friends who were always right there and tolerate my Argentinean explosive temperament. Lady Marian por haberme contenido al principio, por las aventuras en la super city y por haber hecho de tu casa la mia. SuperMerry for trying and really hard to understand the logic of my thoughts, for the loooong walks that exhausted my tongued y

Acknowledgements

porque sos una gran amiga mia!. Mari e Vari as primeiras brasileiras que gostaram de uma argentina, exceto em jogos de futebol!!!. E Vari, não consigo escrever quanto a sua amizade é importante para mim porque sería mais comprida que a minha tese. Mario, you only knows what working with me in Utah means, thanks for share that unique atmosphere. Michi for the lalalas and tralalas. Las hermanas Peru: Yaque y Giova por las chelas compartidas. Arjen for always being next door and for the nice scientific discussions. Markus for tolerating my since the very begging in the lab. Sandy por ser simplemente una tedesca diferente. Arne sharing the office with you was really nice and I think you will miss my sweet voice. Alex for giving always a smile as an answer. Delfi, Kwan, Maaaarten, Martin, Katha, Cori, Daniel and Young Joo for the nice moments.

➤ A Sofia quien estuvo desde el primer día hasta hoy. Porque compartimos más de un crudo invierno y nos bancamos mutuamente en situaciones buenas y malas. Cuando hay un océano que nos separa de nuestra gente, encontrar a alguien como vos hace todo más fácil. Gracias totales.

➤ A mis amigos de allá, esos que conozco desde que empecé a caminar hasta el día de hoy: Iva, Floren, Eri, Vale, Bren, Celi, Juli, Nati, Lore, Andre, Rodri, Isa y Lau. Con ustedes me traje los recuerdos más divertidos de mi vida. Las risas compartidas no se erosionaron con el paso del tiempo y fueron mi droga cuando tuve que afrontar el frio alemán.

➤ A toda la familia que por llamadas, mails y skypeadas siempre estuvo presente. A Valen y mis “sobrinas” (Jose, Malen, Tomi, So, Ju y Marti) por las hermosas obras de arte que decoraron mi cuarto y llenaron mi corazón.

➤ A mis padres y hermanos por haberme apoyado en la decisión. Y haber estado presente en mis momentos más difíciles: cuando era más fácil hacer las valijas estuvieron ahí para recordarme que mi cuarto había sido usurpado. Especialmente a vos Ma que no me dejaste caer.

➤ Rohit ko dhanyawad phir se mere dil ko dhadkane ko. Gracias por haberme aguantado las locuras y no haber salido corriendo.

➤ Sobre todo a mis NONOS que no son doctores ni profesores pero que indudablemente son sabios en temas de familia y amor. Porque son las dos personitas que alimentaron mi corazón constantemente y me dieron fuerzas para seguir.

E-mail: pgilardoni@ice.mpg.de

Research experience

- Molecular Biology: DNA and RNA extraction and quantification. Gel electrophoresis. DNA restriction, cloning methods, DNA sequencing. Diverse PCR methods including quantitative real time PCR. Microarray data analysis. Plant transformation. Mammalian cell culture and mouse dissection.
- Biochemistry: Protein extraction and quantification. SDS-PAGE. Western blot.
- Microbiology: Microorganism isolation and identification. Pathogen inoculation in plants.
- Analytical Chemistry: LC-MS/MS and HPLC instrument operation and data analysis. UPLC/ESI-TOF-MS: general data processing and analysis.
- Ecology: identification of insects and insect damage on plants. Herbivore bioassays

Education

2007-present. Ph.D. student at Department of Molecular Ecology, Max Planck Institute for Chemical Ecology and Friedrich Schiller University, Jena, Germany.

2000-2007. School of Biochemical and Pharmaceutical Sciences, Rosario National University, Rosario, Argentina.

Graduation thesis: **“Regulatory mechanism of the expression of the enzyme CTP:phosphocholine cytidyltransferase isoform β (CT β)”.**

Curriculum vitae

2004. Postgraduate course: "Introduction to Oncology. Cellular and Tumoral Biology". School of Medical Sciences. Rosario National University, Rosario, Argentina.

Publications

- Kallenbach, M., **Gilardoni, P.A.**, Bonaventure, G., Wissgott, A. and Baldwin, I.T. "Eavesdropping on jasmonic acid biosynthesis as criteria for host choice". (Manuscript in preparation)
- **Gilardoni, P.A.**, Hettenhausen, C., Baldwin, I.T. and Bonaventure, G. "The *Nicotiana attenuata* NaLecRK1 gene suppresses the salicylic acid-mediated inhibition of induced defense responses during *Manduca sexta* herbivory". (Submitted to The Plant Cell, PLANTCELL/2011/088229).
- Kallenbach, M., **Gilardoni, P.A.**, Allmann, S., Baldwin, I.T. and Bonaventure, G. "C₁₂ derivatives of the HPL pathway are produced by product-recycling through LOX2 1 in *Nicotiana attenuata* leaves". Accepted for publication in New Phytologist..
- **Gilardoni, P.A.**, Schuck, S., Jüngling, R., Rotter, R., Baldwin, I.T. and Bonaventure, G. "SuperSAGE analysis of the *Nicotiana attenuata* transcriptome after fatty acid-amino acid elicitation (FAC): Identification of early mediators of insect responses". BMC Plant Biol. 10: p.66.
- Marcucci, H., Elena, C., **Gilardoni, P.A.** and Banchio, C. "Characterization of the murine CTP:phosphocholine cytidyltransferase beta gene promoter". Biochim Biophys Acta, 2008. 1781(5): p.254.
- Astronomical Report observation of the "Leonidas meteor shower". MeteorObs. 17.11.96. <http://www.meteorobs.org/maillist/msg02379.html>

Oral presentations

- "LecRK: a novel receptor-like kinase involved in *Nicotiana attenuata*'s defense against *Manduca sexta*". **Gilardoni, P.A.**, Baldwin, I.T., and Bonaventure, G. 15.02.10. 9th IMPRS Symposium, Jena, Germany.

Curriculum vitae

- “Elucidating the role of PNRP, AEP150 and AEP65 in plant defense against herbivores and pathogens. Schuck, S., **Gilardoni, P.A.**, Baldwin, I.T., and Bonaventure, G. 15.02.10. 9th IMPRS Symposium, Jena, Germany.
- “Characterization of a receptor-like kinase of *Nicotiana attenuata*“. **Gilardoni, P.A.**, Baldwin, I.T., and Bonaventure, G. 08-11.11.09. Ringberg Symposium. Kreuth, Germany.
- “Identification of components of the FAC signal transduction pathway in *Nicotiana attenuata*“. **Gilardoni, P.A.**, Baldwin, I.T., and Bonaventure, G. 22.06.09. Institute Symposium 2009. Max Planck Institute for Chemical Ecology. Jena, Germany.
- Marcucci, H., **Gilardoni, P.A.**, Banchio, C. “*Biosynthesis of phosphatidylcholine during neuronal differentiation*“. XLII Annual Meeting of the Argentine Society for Biochemistry and Molecular Biology (SAIB). Rosario, Argentina. 12-15 November 2006.

Poster presentations

- “LecRK: a novel receptor-like kinase involved in *Nicotiana attenuata*'s defense against *Manduca sexta*“. **Gilardoni, P.A.**, Baldwin, I.T., and Bonaventure, G. 07.02.11. 10th IMPRS Symposium, Jena, Germany.
- “Jasmonic acid as a direct defense against herbivores: Empoasca spp. choose their host plants by eavesdropping on aposomatic JA“. Kallenbach, M., **Gilardoni, P.A.**, Bonaventure, G., and Baldwin, I.T. 07.02.11. 10th IMPRS Symposium, Jena, Germany.
- “The transcriptome platform: Next generation sequencing and quantification of mRNA and smRNA“. Gase, K., Gaquerel, E., **Gilardoni, P.A.**, Galis, I., Kroeber, W., Bonaventure, G., Pandey, S., Hahn, T., Gulati, J. and Baldwin, I.T. SAB 2010, Jena, Germany.
- “Signaling in the real world: aposomatic JA signaling, evil lollipops and what the neighbors think about alarm calling“. Kallenbach, M., **Gilardoni, P.A.**, Weinhold, A., Schuman, M., Bonaventure, G., Gaquerel, E., Wissgott, A. and Baldwin, I.T. SAB 2010, Jena, Germany.
- “Profiling the derivatives of the HPL pathway in *N. attenuata*: Hydroxylated C12 alkenal as major product of NaLOX2“. Kallenbach, M., **Gilardoni, P.A.**, Baldwin, I., and Bonaventure, G. 15.02.10. 9th IMPRS Symposium, Jena, Germany.

Curriculum vitae

- “Early transcriptional targets of the FAC signal transduction pathway in *N.attenuata*: a SuperSage approach”. **Gilardoni, P.A.**, Baldwin, I., and Bonaventure, G. 02-03.03.09. 8th Biannual IMPRS Symposium. Max Planck Institute for Chemical Ecology. Jena.
- “Gene expression analysis after FAC elicitation in *Nicotiana attenuata* plants by SuperSAGE”. **Gilardoni, P.A.**, Baldwin, I., and Bonaventure, G. 24-26.08.09. Utrecht Summerschool on Environmental Signalling. Utrecht. The Netherlands.
- “Early transcriptional targets of the FAC signal transduction pathway in *N.attenuata*: a SuperSage approach”. **Gilardoni, P.A.**, Baldwin, I., and Bonaventure, G. 25-26.09.08. Institute Symposium 2008 and 1st MPICE Alumni Meeting. Max Planck Institute for Chemical Ecology. Jena.
- “Identification of the early transcriptional targets of the FAC signal transduction pathway”. **Gilardoni, P.A.**, Baldwin, I., and Bonaventure, G. 25-26.02.08. 7th IMPRS Symposium, Jena, Germany.
- “Mecanismo de regulación de la expresión de la enzima CTP:FOSFOCOLINA CITIDILTRANSFERASA isoforma β ”- **Gilardoni, P.A.**, and Banchio C. VII Congress and XXV Annual Meeting of the Biology Society of Rosario. Rosario, Argentina. 12-14 December 2005.
- “Transcriptional Regulation of Ctp: Phosphocholine Cytidylyltransferase Beta”. **Gilardoni, P.A.**, and Banchio C. X Congress of the Panamerican Association for Biochemistry and Molecular Biology (PABMB), the XLI Annual Meeting of the Argentine Society for Biochemistry and Molecular Biology (SAIB) and the XX Annual Meeting of the Argentine Society for Neurochemistry (SAN). Pinamar, Argentina. 3-6 December 2005.

Selbständigkeitserklärung

Selbständigkeitserklärung

Entsprechend der geltenden, mir bekannten Promotionsordnung der Biologisch-Pharmazeutischen Fakultät der Friedrich-Schiller-Universität Jena erkläre ich, daß ich die vorliegende Dissertation eigenständig angefertigt und alle von mir benutzten Hilfsmittel und Quellen angegeben habe. Personen, die mich bei der Auswahl und Auswertung des Materials sowie bei der Fertigstellung der Manuskripte unterstützt haben, sind am Beginn eines jeden Kapitels genannt. Es wurde weder die Hilfe eines Promotionsberaters in Anspruch genommen, noch haben Dritte für Arbeiten, welche im Zusammenhang mit dem Inhalt der vorliegenden Dissertation stehen, geldwerte Leistungen erhalten. Die vorgelegte Dissertation wurde außerdem weder als Prüfungsarbeit für eine staatliche oder andere wissenschaftliche Prüfung noch als Dissertation an einer anderen Hochschule eingereicht.

Paola Gilardoni
